

# **ADSP-BF60x Blackfin® Processor Hardware Reference**

Preliminary Revision 0.41, June 2012

Part Number  
82-100113-01

Analog Devices, Inc.  
One Technology Way  
Norwood, Mass. 02062-9106

### Preface

|                                                      |          |
|------------------------------------------------------|----------|
| Purpose of This Manual .....                         | -lxxix   |
| Intended Audience .....                              | -lxxix   |
| Manual Contents .....                                | -lxxix   |
| What's New in This Manual .....                      | -lxxxii  |
| Technical or Customer Support .....                  | -lxxxii  |
| Registration for MyAnalog.com .....                  | -lxxxiii |
| EngineerZone .....                                   | -lxxxiii |
| Social Networking Web Sites .....                    | -lxxxiii |
| Supported Processors .....                           | -lxxxiii |
| Product Information .....                            | -lxxxiv  |
| Analog Devices Web Site .....                        | -lxxxiv  |
| CrossCore Embedded Studio Online Documentation ..... | -lxxxiv  |
| Technical Library CD .....                           | -lxxxv   |
| Notation Conventions .....                           | -lxxxv   |
| Register Diagram Conventions .....                   | -lxxxvii |

### Introduction

|                                   |     |
|-----------------------------------|-----|
| Blackfin Processor Core .....     | 1-2 |
| Instruction Set Description ..... | 1-4 |
| Processor Safety Features .....   | 1-5 |
| Dual Core Supervision .....       | 1-5 |

|                                              |      |
|----------------------------------------------|------|
| Fault Management .....                       | 1-5  |
| System Protection .....                      | 1-6  |
| Bandwidth Monitor .....                      | 1-6  |
| Private (to each Core) Memory .....          | 1-6  |
| Shared (by both Cores) Memory .....          | 1-6  |
| I/O Memory Space .....                       | 1-7  |
| Memory Protection .....                      | 1-7  |
| Multi-Parity-Bit-Protected L1 Memories ..... | 1-7  |
| ECC-Protected L2 Memory .....                | 1-7  |
| CRC-Protected Memories .....                 | 1-7  |
| Watchpoint Protection .....                  | 1-8  |
| Pin Multiplexing .....                       | 1-8  |
| Processor Infrastructure .....               | 1-8  |
| System Crossbar (SCB) .....                  | 1-8  |
| Clock Generation .....                       | 1-8  |
| Crystal Oscillator (SYS_XTAL) .....          | 1-9  |
| Clock Out/External Clock .....               | 1-9  |
| System Protection Unit (SPU) .....           | 1-9  |
| Dynamic Power Management (DPM) .....         | 1-10 |
| Core Timers .....                            | 1-10 |
| Event Handling .....                         | 1-11 |
| Core Event Controller (CEC) .....            | 1-11 |
| System Event Controller (SEC) .....          | 1-11 |
| Trigger Routing Unit (TRU) .....             | 1-12 |
| Pin Interrupts .....                         | 1-12 |
| Memory Architecture .....                    | 1-12 |
| Static Memory Controller (SMC) .....         | 1-13 |
| L2 Memory Controller .....                   | 1-13 |
| Dynamic Memory Controller (DMC) .....        | 1-13 |
| Cyclic Redundancy Check (CRC) .....          | 1-14 |

|                                                          |      |
|----------------------------------------------------------|------|
| Direct Memory Access (DMA) .....                         | 1-14 |
| On Chip Peripherals .....                                | 1-15 |
| General-Purpose I/O (GPIO) .....                         | 1-16 |
| General-Purpose Timers .....                             | 1-16 |
| Watchdog Timers .....                                    | 1-16 |
| General-Purpose Counters .....                           | 1-17 |
| Pulsewidth Modulator (PWM) .....                         | 1-17 |
| Universal Asynchronous Receiver/Transmitter (UART) ..... | 1-18 |
| 2-Wire Interface (TWI) .....                             | 1-19 |
| Controller Area Network (CAN) .....                      | 1-19 |
| Universal Serial Bus (USB) .....                         | 1-20 |
| Ethernet Media Access Controller (MAC) .....             | 1-20 |
| Removable Storage Interface (RSI) .....                  | 1-22 |
| Serial Peripheral Interface (SPI) .....                  | 1-22 |
| Serial Port (SPORT) .....                                | 1-22 |
| ADC Control Module (ACM) .....                           | 1-23 |
| Link Port (LP) .....                                     | 1-24 |
| Video Sub-System and Pixel Pipeline (PxP) .....          | 1-24 |
| Pipelined Vision Processor (PVP) .....                   | 1-25 |
| Parallel Peripheral Interface (PPI) .....                | 1-26 |
| Pixel Compositor (PIXC) .....                            | 1-26 |
| Reset Control Unit (RCU) .....                           | 1-27 |
| Booting .....                                            | 1-28 |
| System Design .....                                      | 1-29 |
| System Debug Unit .....                                  | 1-29 |
| System Watchpoint Unit .....                             | 1-29 |

## System Crossbars (SCB)

|                                  |     |
|----------------------------------|-----|
| SCB Features .....               | 2-1 |
| SCB Functional Description ..... | 2-1 |
| SCB Register List .....          | 2-1 |

|                                                             |      |
|-------------------------------------------------------------|------|
| SCB Definitions .....                                       | 2-2  |
| SCB Block Diagram .....                                     | 2-2  |
| SCB Hierarchy Block Diagram .....                           | 2-3  |
| ADSP-BF60x Block Diagram .....                              | 2-3  |
| SCB Arbitration Tables .....                                | 2-4  |
| SCB Units, Master Interfaces, and Arbitration Types .....   | 2-5  |
| SCB0 Slots and Masters .....                                | 2-6  |
| SCB1 Slots and Masters .....                                | 2-14 |
| SCB2 Slots and Masters .....                                | 2-15 |
| SCB3 Slots and Masters .....                                | 2-16 |
| SCB4 Slots and Masters .....                                | 2-17 |
| SCB5 Slots and Masters .....                                | 2-17 |
| SCB6 Slots and Masters .....                                | 2-18 |
| SCB7 Slots and Masters .....                                | 2-18 |
| SCB8 Slots and Masters .....                                | 2-19 |
| SCB9 Slots and Masters .....                                | 2-19 |
| SCB Programming Model .....                                 | 2-20 |
| SCB Register Access Restrictions .....                      | 2-20 |
| SCB Programming Concepts .....                              | 2-20 |
| Arbitration Model Configuration .....                       | 2-20 |
| SCB Programming Examples .....                              | 2-21 |
| SCB Register Descriptions .....                             | 2-21 |
| Arbitration Read Channel Master Interface n Register .....  | 2-21 |
| Arbitration Write Channel Master Interface n Register ..... | 2-22 |
| Slave Interfaces Number Register .....                      | 2-23 |
| Master Interfaces Number Register .....                     | 2-24 |

## **Clock Generation Unit (CGU)**

|                                     |     |
|-------------------------------------|-----|
| CGU Functional Description .....    | 3-1 |
| CGU Register List .....             | 3-1 |
| ADSP-BF60x CGU Interrupt List ..... | 3-2 |

|                                                                                          |      |
|------------------------------------------------------------------------------------------|------|
| ADSP-BF60x CGU Trigger List .....                                                        | 3-2  |
| CGU Definitions .....                                                                    | 3-3  |
| CGU PLL Block Diagram .....                                                              | 3-3  |
| CGU Event Control .....                                                                  | 3-5  |
| CGU Event .....                                                                          | 3-5  |
| CGU Error .....                                                                          | 3-5  |
| CGU Generated Bus Errors .....                                                           | 3-6  |
| CGU Programming Model .....                                                              | 3-6  |
| CGU Mode Configuration .....                                                             | 3-6  |
| Changing the PLLCLK Frequency .....                                                      | 3-7  |
| Changing the CCLKn, SYSCLK, or SCLKn frequency Without Modifying the PLLCLK Frequency .. | 3-7  |
| Changing the DCLK Clock Frequency .....                                                  | 3-8  |
| Changing the OUTCLK Frequency .....                                                      | 3-9  |
| Aligning All Clocks .....                                                                | 3-9  |
| Valid ADSP-BF60x CGU_CTL.MSEL Bit Settings .....                                         | 3-10 |
| CGU Register Descriptions .....                                                          | 3-10 |
| Control Register .....                                                                   | 3-10 |
| Status Register .....                                                                    | 3-12 |
| Divisor Register .....                                                                   | 3-17 |
| CLKOUT Select Register .....                                                             | 3-20 |

## System Protection Unit (SPU)

|                                  |     |
|----------------------------------|-----|
| SPU Features .....               | 4-1 |
| SPU Functional Description ..... | 4-1 |
| SPU Register List .....          | 4-4 |
| SPU Definitions .....            | 4-4 |
| SPU Block Diagram .....          | 4-4 |
| SPU Architectural Concepts ..... | 4-5 |
| SPU Event Control .....          | 4-5 |
| SPU Programming Model .....      | 4-5 |
| SPU Mode Configuration .....     | 4-6 |

|                                       |      |
|---------------------------------------|------|
| Locking Write-Protect Registers ..... | 4-6  |
| Protecting a Peripheral .....         | 4-7  |
| SPU Register Descriptions .....       | 4-7  |
| Control Register .....                | 4-7  |
| Status Register .....                 | 4-8  |
| Write Protect Register n .....        | 4-10 |

## Dynamic Power Management (DPM)

|                                                                              |      |
|------------------------------------------------------------------------------|------|
| DPM Features .....                                                           | 5-1  |
| DPM Functional Description .....                                             | 5-1  |
| DPM Register List .....                                                      | 5-1  |
| ADSP-BF60x DPM Interrupt List .....                                          | 5-2  |
| DPM Definitions .....                                                        | 5-3  |
| DPM Operating Modes .....                                                    | 5-3  |
| RESET .....                                                                  | 5-4  |
| FULL-ON .....                                                                | 5-4  |
| ACTIVE .....                                                                 | 5-4  |
| ACTIVE with PLL Disabled .....                                               | 5-4  |
| DEEP SLEEP .....                                                             | 5-4  |
| HIBERNATE .....                                                              | 5-5  |
| Ensuring VDD_INT is Restored Before Booting .....                            | 5-6  |
| Using the Power Good Counter to Ensure That Internal Power is Restored ..... | 5-7  |
| Using SYS_PWRGD to Ensure That VDD_INT is Restored .....                     | 5-8  |
| DPM Event Control .....                                                      | 5-8  |
| DPM Events .....                                                             | 5-8  |
| DPM Errors .....                                                             | 5-8  |
| Configuring DPM DEEP SLEEP Mode .....                                        | 5-9  |
| Configuring DPM HIBERNATE Mode .....                                         | 5-9  |
| ADSP-BF60x Wake-Up Sources .....                                             | 5-10 |
| ADSP-BF60x Clock Buffer Disable Bit Assignments .....                        | 5-11 |

| ADSP-BF60x PINT Trigger List .....               | 14-12 |
| PORT Definitions .....                           | 14-13 |
| PORT Architectural Concepts .....                | 14-13 |
| External Interfaces .....                        | 14-13 |
| Internal Interfaces .....                        | 14-14 |
| PORT Event Control .....                         | 14-14 |
| PORT Interrupt Signals .....                     | 14-14 |
| PORT Programming Model .....                     | 14-16 |
| PORT Register Descriptions .....                 | 14-19 |
| Port x Function Enable Register .....            | 14-20 |
| Port x Function Enable Set Register .....        | 14-24 |
| Port x Function Enable Clear Register .....      | 14-27 |
| Port x GPIO Data Register .....                  | 14-30 |
| Port x GPIO Data Set Register .....              | 14-34 |
| Port x GPIO Data Clear Register .....            | 14-38 |
| Port x GPIO Direction Register .....             | 14-42 |
| Port x GPIO Direction Set Register .....         | 14-46 |
| Port x GPIO Direction Clear Register .....       | 14-50 |
| Port x GPIO Input Enable Register .....          | 14-54 |
| Port x GPIO Input Enable Set Register .....      | 14-58 |
| Port x GPIO Input Enable Clear Register .....    | 14-61 |
| Port x Multiplexer Control Register .....        | 14-65 |
| Port x GPIO Input Enable Toggle Register .....   | 14-67 |
| Port x GPIO Polarity Invert Register .....       | 14-71 |
| Port x GPIO Polarity Invert Set Register .....   | 14-76 |
| Port x GPIO Polarity Invert Clear Register ..... | 14-79 |
| Port x GPIO Lock Register .....                  | 14-83 |
| Port x GPIO Revision ID .....                    | 14-85 |

|                                  |        |
|----------------------------------|--------|
| PINT Register Descriptions ..... | 14-86  |
| Pint Mask Set Register .....     | 14-86  |
| Pint Mask Clear Register .....   | 14-90  |
| Pint Request Register .....      | 14-94  |
| Pint Assign Register .....       | 14-98  |
| Pint Edge Set Register .....     | 14-99  |
| Pint Edge Clear Register .....   | 14-103 |
| Pint Invert Set Register .....   | 14-107 |
| Pint Invert Clear Register ..... | 14-111 |
| Pint Pinstate Register .....     | 14-115 |
| Pint Latch Register .....        | 14-119 |

## General-Purpose Timer (TIMER)

|                                                              |       |
|--------------------------------------------------------------|-------|
| TIMER Features .....                                         | 15-1  |
| TIMER Register List .....                                    | 15-2  |
| ADSP-BF60x TIMER Interrupt List .....                        | 15-3  |
| ADSP-BF60x TIMER Trigger List .....                          | 15-3  |
| TIMER Internal Interface .....                               | 15-5  |
| TIMER External Interface .....                               | 15-5  |
| TIMER General Operation .....                                | 15-5  |
| Timer Period, Width and Delay Register Interaction .....     | 15-6  |
| TIMER Programming Concepts .....                             | 15-8  |
| Setting Up Constantly Changing Timer Conditions .....        | 15-8  |
| Configuring, Enabling and Disabling One or More Timers ..... | 15-8  |
| Configuring Timer Data and Status Interrupts .....           | 15-9  |
| Using the Timer Broadcast Feature .....                      | 15-9  |
| Timer Single-Pulse PWMOUT Mode .....                         | 15-9  |
| Timer Continuous PWMOUT Mode .....                           | 15-10 |
| TIMER Width Capture (WIDCAP) Mode .....                      | 15-11 |
| GP Timer Width Capture Mode Overflow .....                   | 15-15 |
| TIMER Windowed Watchdog (WATCHDOG) Modes .....               | 15-17 |

|                                           |       |
|-------------------------------------------|-------|
| Timer Windowed Watchdog Width Mode .....  | 15-18 |
| Timer Windowed Watchdog Period Mode ..... | 15-20 |
| TIMER Pin Interrupt (PININT) Mode .....   | 15-21 |
| TIMER External Clock (EXTCLK) Mode .....  | 15-22 |
| Timer Illegal States .....                | 15-23 |
| Continuous PWMOUT Mode .....              | 15-24 |
| Single Pulse PWMOUT Mode .....            | 15-25 |
| WID CAP Mode .....                        | 15-26 |
| EXTCLK Mode .....                         | 15-26 |

## Watchdog Timer (WDOG)

|                                             |      |
|---------------------------------------------|------|
| WDOG Features .....                         | 16-1 |
| Watchdog Timer Functional Description ..... | 16-1 |
| WDOG Register List .....                    | 16-2 |
| ADSP-BF60x WDOG Interrupt List .....        | 16-2 |
| WDOG Block Diagram .....                    | 16-2 |
| Internal Interface .....                    | 16-3 |
| External Interface .....                    | 16-3 |
| WDOG Configuration .....                    | 16-3 |
| WDOG Register Descriptions .....            | 16-4 |
| Control Register .....                      | 16-4 |
| Count Register .....                        | 16-5 |
| Watchdog Timer Status Register .....        | 16-6 |

## General-Purpose Counter (CNT)

|                                     |      |
|-------------------------------------|------|
| CNT Features .....                  | 17-1 |
| CNT Functional Description .....    | 17-1 |
| CNT Register List .....             | 17-2 |
| ADSP-BF60x CNT Interrupt List ..... | 17-3 |
| ADSP-BF60x CNT Trigger List .....   | 17-3 |
| CNT Operating Modes .....           | 17-4 |
| Quadrature Encoder Mode .....       | 17-4 |
| Binary Encoder Mode .....           | 17-4 |
| Up/Down Counter Mode .....          | 17-5 |
| Direction Counter Mode .....        | 17-5 |
| Timed Direction Mode .....          | 17-5 |
| CNT Event Control .....             | 17-5 |

|                                                                 |       |
|-----------------------------------------------------------------|-------|
| Illegal Gray/Binary Code Events .....                           | 17-6  |
| Up/Down Count Events .....                                      | 17-6  |
| Zero-Count Events .....                                         | 17-6  |
| Overflow Events .....                                           | 17-6  |
| Boundary Match Events .....                                     | 17-7  |
| Zero Marker Events .....                                        | 17-7  |
| CNT Programming Model .....                                     | 17-7  |
| CNT General Programming Flow .....                              | 17-7  |
| CNT Mode Configuration .....                                    | 17-7  |
| Configuring GP Counter Push-button Operation .....              | 17-8  |
| Configuring Zero-Marker-Zeros-Counter Mode .....                | 17-8  |
| Configuring Zero-Marker-Error Mode .....                        | 17-8  |
| Configuring Zero-Once Mode .....                                | 17-9  |
| Configuring Boundary Auto-Extend Mode .....                     | 17-9  |
| Configuring Boundary Capture Mode .....                         | 17-9  |
| Configuring Boundary Compare and Boundary Zero Modes .....      | 17-10 |
| CNT Programming Concepts .....                                  | 17-10 |
| CNT Input Noise Filtering .....                                 | 17-10 |
| Capturing Counter Interval and CNT_CNTR Read Timing .....       | 17-11 |
| Capturing Time Interval Between Successive Counter Events ..... | 17-13 |
| CNT Register Descriptions .....                                 | 17-14 |
| Configuration Register .....                                    | 17-14 |
| Interrupt Mask Register .....                                   | 17-17 |
| Status Register .....                                           | 17-20 |
| Command Register .....                                          | 17-21 |
| Debounce Register .....                                         | 17-23 |
| Counter Register .....                                          | 17-26 |
| Maximum Count Register .....                                    | 17-26 |
| Minimum Count Register .....                                    | 17-27 |

## Pulse-Width Modulator (PWM)

|                                                                          |       |
|--------------------------------------------------------------------------|-------|
| PWM Features .....                                                       | 18-1  |
| PWM Register List .....                                                  | 18-1  |
| ADSP-BF60x PWM Interrupt List .....                                      | 18-3  |
| ADSP-BF60x PWM Trigger List .....                                        | 18-4  |
| Functional Description .....                                             | 18-4  |
| Architectural Concepts .....                                             | 18-5  |
| Block Diagram .....                                                      | 18-5  |
| Timer Units .....                                                        | 18-6  |
| PWM Switching Frequency (PWM_TM) Register .....                          | 18-7  |
| Timer Unit Operation .....                                               | 18-7  |
| Phase Offset Control .....                                               | 18-9  |

| Peripheral Mode, ISO IN, Large MaxPktSize .....                           | 22-30 |
| Peripheral Mode, Bulk OUT, Transfer Size Known .....                      | 22-30 |
| Peripheral Mode, Bulk OUT, Transfer Size Unknown .....                    | 22-31 |
| Peripheral Mode, ISO OUT, Small MaxPktSize .....                          | 22-31 |
| Peripheral Mode, ISO OUT, Large MaxPktSize .....                          | 22-32 |
| Peripheral Mode Suspend .....                                             | 22-32 |
| Start-of-frame (SOF) Packets .....                                        | 22-32 |
| Soft Connect/Soft Disconnect .....                                        | 22-33 |
| Error Handling As a Peripheral .....                                      | 22-33 |
| Stalls Issued to Control Transfers .....                                  | 22-34 |
| Zero Length OUT Data Packets in Control Transfers .....                   | 22-34 |
| USB Host Mode .....                                                       | 22-34 |
| Transaction Scheduling .....                                              | 22-35 |
| Endpoint Setup and Data Transfer .....                                    | 22-35 |
| Control Transaction as a Host .....                                       | 22-35 |
| Setup Phase as a Host .....                                               | 22-36 |
| IN Data Phase as a Host .....                                             | 22-37 |
| OUT Data as a Host (Control) .....                                        | 22-37 |
| IN Status Phase as a Host (Following SETUP Phase or OUT Data Phase) ..... | 22-38 |

|                                                                                       |       |
|---------------------------------------------------------------------------------------|-------|
| OUT Status Phase as a Host (following IN Data Phase) .....                            | 22-39 |
| Host IN Transactions .....                                                            | 22-39 |
| Host OUT Transactions .....                                                           | 22-40 |
| Multi-point Support .....                                                             | 22-40 |
| Allocating Devices to Endpoints .....                                                 | 22-40 |
| Multi-point Operation .....                                                           | 22-41 |
| Multi-point Bandwidth Considerations .....                                            | 22-42 |
| Babble Interrupt .....                                                                | 22-42 |
| VBUS Events .....                                                                     | 22-43 |
| Actions as an “A” Device .....                                                        | 22-43 |
| Actions as a “B” Device .....                                                         | 22-44 |
| Host Mode Reset .....                                                                 | 22-44 |
| Host Mode Suspend .....                                                               | 22-44 |
| Suspending and Resuming the Controller .....                                          | 22-45 |
| Suspend/Resume By Inactivity On The USB Bus (L0 To L2 State) In Peripheral Mode ..... | 22-45 |
| Suspend/Resume By Inactivity On The USB Bus (L0 To L2 State) In Host Mode .....       | 22-46 |
| Suspend/Resume By an LPM Transaction (L0 To L1 State) In Peripheral Mode .....        | 22-46 |
| Suspend/Resume by an LPM Transaction (L0 to L1 State) in Host Mode .....              | 22-48 |
| USB Event Control .....                                                               | 22-49 |
| USB Interrupt Signals .....                                                           | 22-49 |
| Interrupt Handling .....                                                              | 22-51 |
| USB Reset Signals .....                                                               | 22-53 |
| USB Reset in Peripheral Mode .....                                                    | 22-53 |
| USB Reset in Host Mode .....                                                          | 22-53 |
| USB Programming Model .....                                                           | 22-54 |
| Peripheral Mode Flow Charts .....                                                     | 22-54 |
| Host Mode Flow Charts .....                                                           | 22-62 |
| DMA Mode Flow Charts .....                                                            | 22-71 |
| OTG Session Request .....                                                             | 22-76 |
| Starting a Session .....                                                              | 22-77 |

|                                                |        |
|------------------------------------------------|--------|
| Detecting Activity .....                       | 22-77  |
| Host Negotiation/Configuration .....           | 22-78  |
| Wakeup from Hibernate State .....              | 22-78  |
| Data Transfer .....                            | 22-79  |
| Loading/Unloading Packets from Endpoints ..... | 22-80  |
| DMA Master Channels .....                      | 22-80  |
| DMA Bus Cycles .....                           | 22-81  |
| Transferring Packets Using DMA .....           | 22-83  |
| Individual Packet: RX Endpoint .....           | 22-83  |
| Individual Packet: TX Endpoint .....           | 22-83  |
| Multiple Packets: RX Endpoint .....            | 22-84  |
| Multiple Packets: TX Endpoints .....           | 22-85  |
| USB Register Descriptions .....                | 22-85  |
| Function Address Register .....                | 22-88  |
| Power and Device Control Register .....        | 22-89  |
| Transmit Interrupt Register .....              | 22-92  |
| Receive Interrupt Register .....               | 22-95  |
| Transmit Interrupt Enable Register .....       | 22-98  |
| Receive Interrupt Enable Register .....        | 22-102 |
| Common Interrupts Register .....               | 22-104 |
| Common Interrupts Enable Register .....        | 22-107 |
| Frame Number Register .....                    | 22-109 |
| Index Register .....                           | 22-110 |
| Testmode Register .....                        | 22-111 |
| FIFO Byte (8-Bit) Register .....               | 22-112 |
| FIFO Half-Word (16-Bit) Register .....         | 22-113 |
| FIFO Word (32-Bit) Register .....              | 22-113 |
| Device Control Register .....                  | 22-114 |
| Transmit FIFO Size Register .....              | 22-116 |
| Receive FIFO Size Register .....               | 22-118 |

|                                                                   |        |
|-------------------------------------------------------------------|--------|
| Transmit FIFO Address Register .....                              | 22-120 |
| Receive FIFO Address Register .....                               | 22-121 |
| Endpoint Information Register .....                               | 22-122 |
| RAM Information Register .....                                    | 22-123 |
| Link Information Register .....                                   | 22-123 |
| VBUS Pulse Length Register .....                                  | 22-124 |
| High-Speed EOF 1 Register .....                                   | 22-125 |
| Full-Speed EOF 1 Register .....                                   | 22-125 |
| Low-Speed EOF 1 Register .....                                    | 22-126 |
| Software Reset Register .....                                     | 22-126 |
| MPn Transmit Function Address Register .....                      | 22-127 |
| MPn Transmit Hub Address Register .....                           | 22-128 |
| MPn Transmit Hub Port Register .....                              | 22-129 |
| MPn Receive Function Address Register .....                       | 22-130 |
| MPn Receive Hub Address Register .....                            | 22-130 |
| MPn Receive Hub Port Register .....                               | 22-131 |
| EPn Transmit Maximum Packet Length Register .....                 | 22-131 |
| EP0 Configuration and Status (Host) Register .....                | 22-132 |
| EP0 Configuration and Status (Peripheral) Register .....          | 22-136 |
| EPn Transmit Configuration and Status (Host) Register .....       | 22-139 |
| EPn Transmit Configuration and Status (Peripheral) Register ..... | 22-144 |
| EPn Receive Maximum Packet Length Register .....                  | 22-149 |
| EPn Receive Configuration and Status (Host) Register .....        | 22-150 |
| EPn Receive Configuration and Status (Peripheral) Register .....  | 22-155 |
| EP0 Number of Received Bytes Register .....                       | 22-161 |
| EPn Number of Bytes Received Register .....                       | 22-161 |
| EPn Transmit Type Register .....                                  | 22-162 |
| EP0 Connection Type Register .....                                | 22-164 |
| EP0 NAK Limit Register .....                                      | 22-165 |
| EPn Transmit Polling Interval Register .....                      | 22-166 |

|                                                 |        |
|-------------------------------------------------|--------|
| EPn Receive Type Register .....                 | 22-167 |
| EPn Receive Polling Interval Register .....     | 22-169 |
| EP0 Configuration Information Register .....    | 22-170 |
| DMA Interrupt Register .....                    | 22-173 |
| DMA Channel n Control Register .....            | 22-175 |
| DMA Channel n Address Register .....            | 22-178 |
| DMA Channel n Count Register .....              | 22-179 |
| EPn Request Packet Count Register .....         | 22-180 |
| Chirp Timeout Register .....                    | 22-180 |
| Host High Speed Return to Normal Register ..... | 22-181 |
| High Speed Timeout Register .....               | 22-182 |
| LPM Attribute Register .....                    | 22-182 |
| LPM Control Register .....                      | 22-184 |
| LPM Interrupt Enable Register .....             | 22-186 |
| LPM Interrupt Status Register .....             | 22-188 |
| LPM Function Address Register .....             | 22-191 |
| VBUS Control Register .....                     | 22-192 |
| Battery Charging Control Register .....         | 22-193 |
| PHY Control Register .....                      | 22-194 |
| PLL and Oscillator Control Register .....       | 22-195 |

## Ethernet Media Access Controller (EMAC)

|                                         |       |
|-----------------------------------------|-------|
| Overview .....                          | 23-1  |
| Introduction .....                      | 23-1  |
| EMAC Features .....                     | 23-2  |
| EMAC Functional Description .....       | 23-2  |
| EMAC Register List .....                | 23-3  |
| ADSP-BF60x EMAC Interrupt List .....    | 23-9  |
| EMAC Definitions .....                  | 23-10 |
| EMAC Block Diagram and Interfaces ..... | 23-10 |
| EMAC CORE Sub-blocks .....              | 23-12 |

|                                                 |       |
|-------------------------------------------------|-------|
| PHY Interface .....                             | 23-14 |
| EMAC Clock Sources .....                        | 23-15 |
| EMAC Architectural Concepts .....               | 23-16 |
| EMAC System Crossbar Interface (EMAC SCB) ..... | 23-16 |
| Priority of SCB Requests .....                  | 23-17 |
| SCB Interface Programming Options .....         | 23-18 |
| DMA Bursts with SCB Interface .....             | 23-19 |
| SCB Bus Transaction Status .....                | 23-20 |
| Fatal Bus Error .....                           | 23-20 |
| EMAC DMA Controller (EMAC DMA) .....            | 23-20 |
| DMA Related Registers .....                     | 23-21 |
| DMA Descriptors .....                           | 23-23 |
| Transmit Descriptor .....                       | 23-24 |
| Receive Descriptor .....                        | 23-29 |
| EMAC DMA Transmit Process .....                 | 23-36 |
| Default (Non-OSF) Mode .....                    | 23-36 |
| OSF Mode Enabled .....                          | 23-37 |
| Transmit Frame Processing .....                 | 23-38 |
| Transmit Polling Suspended .....                | 23-38 |
| EMAC DMA Receive Process .....                  | 23-39 |
| Receive Frame Processing .....                  | 23-40 |
| Receive Descriptor Acquisition .....            | 23-40 |
| Receive Process Suspended .....                 | 23-41 |
| OWN Bit (Ownership) Semaphore .....             | 23-41 |
| Application Data Buffer Alignment .....         | 23-42 |
| Buffer Size Calculations .....                  | 23-42 |
| EMAC FIFO Layer (EMAC MFL) .....                | 23-43 |
| FIFO Size .....                                 | 23-43 |
| FIFO Layer Transmit Path .....                  | 23-43 |
| FIFO Layer Receive Path .....                   | 23-44 |

|                                                         |       |
|---------------------------------------------------------|-------|
| EMAC CORE .....                                         | 23-45 |
| EMAC CORE Transmission Engine .....                     | 23-48 |
| EMAC CORE Reception Engine .....                        | 23-52 |
| EMAC Station Management Interface (SMI) .....           | 23-59 |
| MDC Clock Frequency .....                               | 23-60 |
| SMI Write Operation .....                               | 23-62 |
| SMI Read Operation .....                                | 23-62 |
| EMAC Management Counters (MMC) .....                    | 23-63 |
| MMC Receive Interrupt Register .....                    | 23-64 |
| MMC Transmit Interrupt Register .....                   | 23-64 |
| MMC Receive Checksum Offload Interrupt Register .....   | 23-65 |

Count Register n ..... 36-23

Target Register n ..... 36-24

Bandwidth History Register n ..... 36-25

Current Register n ..... 36-25

**Index**

# Preface

Thank you for purchasing and developing systems using an enhanced Blackfin processor from Analog Devices.

## Purpose of This Manual

The *ADSP-BF60x Blackfin Processor Hardware Reference* provides architectural information about the ADSP-BF60x processors. This hardware reference provides the main architectural information about these processors. The architectural descriptions cover functional blocks, buses, and ports, including all features and processes that they support. For programming information, see the *Blackfin Processor Programming Reference*. For timing, electrical, and package specifications, see the *ADSP-BF60x Blackfin Processor Data Sheet*.

## Intended Audience

The primary audience for this manual is a programmer who is familiar with Analog Devices processors. The manual assumes the audience has a working knowledge of the appropriate processor architecture and instruction set. Programmers who are unfamiliar with Analog Devices processors can use this manual, but should supplement it with other texts, such as hardware reference and programming reference books, that describe their target architecture.

## Manual Contents

This manual consists of the following chapters:

- Preface
- Introduction — Provides a high level overview of the processor, including peripherals, power management, and development tools.
- System Cross Bar (SCB) — Describes on-chip buses, including how data moves through the system.
- Clock Generation Unit (CGU) — Describes the phase locked loop (PLL), PLL control unit (PCU), and CGU, which generate on-chip clocks.
- System Protection Unit (SPU) — Describes the system protection and how the SPU protects system resources from errant writes.

- Dynamic Power Management (DPM) — Describes the clocking, including the PLL, and the dynamic power management controller.
- Core Timers (TMR) — Each processor core has its own dedicated timer. The core timer is clocked by the internal processor clock and is typically used as a system tick clock for generating periodic operating system interrupts.
- System Event Controller (SEC) — Describes the system peripheral interrupts, including setup and clearing of interrupt requests.
- Trigger Routing Unit (TRU) — Describes TRU operations providing system-level sequence control without core intervention.
- Static Memory Controller (SMC) — Describes the static (SRAM) memory controller of the processor and the asynchronous memory interface.
- L2 Memory Controller (L2CTL) — Describes the memory controller and its operation.
- Dynamic Memory Controller (DMC) — Describes the dynamic (DDR2) memory controller of the processor, related registers, configuration, and commands.
- Cyclic Redundancy Check (CRC) — Describes the CRC operations on blocks of data presented to the peripheral.
- DMA Channel (DMA) — Describes the peripheral DMA and Memory DMA controllers, including topics such as performance, software management of DMA, and DMA errors.
- General-Purpose Ports (PORTS) — Describes the general-purpose I/O ports, including the structure of each port, multiplexing, configuring the pins, and generating interrupts.
- Pin Interrupts (PINT) — Describes operation of port pins on the processor, which can request interrupts in either an edge-sensitive or a level-sensitive manner with programmable polarity.
- General-Purpose Timer (TIMER) — Describes the general-purpose timers that can be configured in any of three modes; the core timer that can generate periodic interrupts for a variety of timing functions; and the watchdog timer that can implement software watchdog functions, such as generating events to the Blackfin processor core.
- Watchdog Timer (WDOG) — Describes the watchdog timer.
- General-Purpose Counter (CNT) — Describes the Rotary (up/down) Counter. This counter provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial or motor-control type of wheels.
- Pulsewidth Modulator (PWM) — Describes the The PWM controller—a flexible, programmable, three-phase PWM waveform generator that can be programmed to generate the required switching patterns to drive a three-phase voltage source inverter for ac induction motor (ACIM) or permanent magnet synchronous motor (PMSM) control.

- Universal Async Rx/Tx (UART) — Describes the Universal Asynchronous Receiver/Transmitter port that converts data between serial and parallel formats. The UART supports the half-duplex IrDA SIR protocol as a mode-enabled feature.
- Two Wire Interface (TWI) — Describes the Two Wire Interface (TWI) controller, which allows a device to interface to an Inter IC bus as specified by the *Philips I<sup>2</sup>C Bus Specification version 2.1* dated January 2000.
- Controller Area Network (CAN) — Describes the CAN module, a low bit rate serial interface intended for use in applications where bit rates are typically up to 1Mbit/s.
- Universal Serial Bus (USB) — Describes the USB OTG interface of the processor. This interface provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras and MP3 players, allowing these devices to transfer data via a point-to-point USB connection without the need for a PC host.
- 10/100 Ethernet MAC (EMAC) — Describes the Ethernet Media Access Controller (MAC) peripheral that provides a 10/100M bit/s Ethernet interface, compliant to IEEE Std. 802.3-2002, between an MII (Media Independent Interface) and the Blackfin peripheral subsystem. Also, describes the IEEE 1588 engine module and the module's operation.
- Removable Storage Interface (RSI) — Describes the RSI interface for multimedia cards (MMC), secure digital memory cards (SD), secure digital input/output cards (SDIO) and consumer electronic ATA devices (CE-ATA).
- Serial Peripheral Interface (SPI) — Describes the Serial Peripheral Interface (SPI) port that provides an I/O interface to a variety of SPI compatible peripheral devices.
- Serial Port (SPORT) — Describes the independent, synchronous Serial Port Controller which provides an I/O interface to a variety of serial peripheral devices.
- ADC Control Module (ACM) — Describes the ADC control module (ACM), which provides an interface to synchronize the controls between the processor and an analog-to-digital converter (ADC) module.
- Link Port (LP) — Describes the two bidirectional 8-bit wide link ports, which can connect to other processor or peripheral link ports.
- Video Subsystem (VID) — Describes the subsystem's connectivity matrix that interconnects the video related peripherals.
- Pipelined Vision Processor (PVP) — Describes the PVP's support for co-processing and pre-processing of monochrome video frames in ADAS applications, robotic systems, and other machine applications.
- Parallel Peripheral Interface (PPI) — Describes the Parallel Peripheral Interface (PPI) of the processor. The PPI is a half-duplex, bidirectional port accommodating up to 16 bits of data and is used for digital video and data converter applications.

- Pixel Compositor (PIXC) — Describes the PIXC, which provides data overlay, transparent color, and color space conversion support for active (TFT) flat-panel digital color/monochrome LCD displays or analog NTSC/PAL video output.
- Reset Control Unit (RCU)
- Booting — Describes the booting methods, booting process and specific boot modes for the processor.
- System Design — Describes how to use the processor as part of an overall system. It includes information about bus timing and latency numbers, semaphores, and a discussion of the treatment of unused pins.
- Test Features — Describes test features for the processor, discusses the JTAG standard, boundary-scan architecture, instruction and boundary registers, and public instructions.
  - System Debug Unit (SDU)
  - System Watchpoint Unit (SWU)

## What's New in This Manual

This revision (0.4) is a preliminary revision of the *ADSP-BF60x Blackfin Processor Hardware Reference*. This revision adds the register information for the SCB, TMR, DPM, L2CTL, PWM, USB, and CAN chapters. Also, this revision adds supplementary information and corrections throughout the text.

## Technical or Customer Support

You can reach Analog Devices, Inc. Customer Support in the following ways:

- Visit the Embedded Processing and DSP products Web site at [http://www.analog.com/processors/technical\\_support](http://www.analog.com/processors/technical_support)
- E-mail tools questions to <http://mailto:processor.tools.support@analog.com>
- E-mail processor questions to <http://mailto:processor.support@analog.com> (world wide support) or <http://mailto:processor.china@analog.com> (China support)
- Phone questions to 1-800-ANALOGD
- Contact your Analog Devices, Inc. local sales office or authorized distributor
- Send questions by mail to:

Analog Devices, Inc.  
One Technology Way  
P.O. Box 9106  
Norwood, MA 02062-9106 USA

## Registration for MyAnalog.com

[MyAnalog.com](#) is a free feature of the Analog Devices Web site that allows customizing a Web page to display only the latest information about products you are interested in. Click **Register** to use this site. Registration takes about five minutes and serves as a means to select the information you want to receive.

If you are already a registered user, just log on. Your user name is your e-mail address.

## EngineerZone

[EngineerZone](#) is a technical support forum from Analog Devices. It allows you direct access to ADI technical support engineers. You can search FAQs and technical information to get quick answers to your embedded processing and DSP design questions.

Use EngineerZone to connect with other DSP developers who face similar design challenges. You can also use this open forum to share knowledge and collaborate with the ADI support team and your peers. Visit <http://ez.analog.com/welcome> to sign up.

## Social Networking Web Sites

You can now follow Analog Devices news on Twitter and Analog Devices Blackfin products on LinkedIn. To access:

- Twitter: [https://twitter.com/#!/adi\\_news](https://twitter.com/#!/adi_news)
- LinkedIn: <http://www.linkedin.com/groups Analog Devices Blackfin>

## Supported Processors

The following is the list of Analog Devices, Inc. processors supported in CrossCore Embedded Studio® development tools.

### Blackfin (ADSP-BFxxx) Processors

The name *Blackfin* refers to a family of 16-bit, embedded processors. CrossCore Embedded Studio currently supports the following Blackfin families ADSP-BF50x, ADSP-BF51x, ADSP-BF52x, ADSP-BF53x, ADSP-BF54x, ADSP-BF59x, ADSP-BF561, and ADSP-BF60x processors.

### SHARC® (ADSP-21xxx) Processors

The name *SHARC* refers to a family of high-performance, 32-bit, floating-point processors that can be used in speech, sound, graphics, and imaging applications. CrossCore Embedded Studio currently supports the following SHARC families: ADSP-2106x, ADSP-2116x, ADSP-2126x, ADSP-2136x, and ADSP-214xx.

## Product Information

Product information can be obtained from the Analog Devices Web site and CrossCore Embedded Studio online Help system.

## Analog Devices Web Site

The Analog Devices Web site, <http://www.analog.com>, provides information about a broad range of products-analog integrated circuits, amplifiers, converters, and digital signal processors.

To access a complete technical library for each processor family, go to [http://www.analog.com/processors/technical\\_library](http://www.analog.com/processors/technical_library). The manuals selection opens a list of current manuals related to the product as well as a link to the previous revisions of the manuals. When locating your manual title, note a possible errata check mark next to the title that leads to the current correction report against the manual.

Also note, [MyAnalog.com](http://www.analog.com) is a free feature of the Analog Devices Web site that allows customizing a Web page to display only the latest information on products you are interested in. You can also choose to receive weekly e-mail notifications containing updates to the Web pages that meet your interests, including documentation errata against all manuals. [MyAnalog.com](http://www.analog.com) provides access to books, application notes, data sheets, code examples, and more.

Visit [MyAnalog.com](http://www.analog.com) to sign up. If you are already a registered user, just log on. Your user name is your e-mail address.

## CrossCore Embedded Studio Online Documentation

Online documentation comprises the CrossCore Embedded Studio help system, software tools manuals, hardware tools manuals, processor manuals, Dinkum Abridged C++ library, and FLEXnet License Tools software documentation. You can search easily across the entire CrossCore Embedded Studio documentation set for any topic of interest.

For easy printing, supplementary Portable Documentation Format (.pdf) files for all manuals are provided on the CrossCore Embedded Studio product page on the Analog Devices website.

Each documentation file type is described as follows.

| File | Description                                            |
|------|--------------------------------------------------------|
| .chm | Help system files and manuals in Microsoft help format |

| File          | Description                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .htm or .html | Dinkum Abridged C++ library and FLEXnet License Tools software documentation. Viewing and printing the .html files requires a browser, such as Internet Explorer 6.0 (or higher). |
| .pdf          | CrossCore Embedded Studio and processor manuals in PDF format. Viewing and printing the .pdf files requires a PDF reader, such as Adobe Acrobat Reader (9.0 or higher).           |

## Technical Library CD

The technical library CD contains seminar materials, product highlights, a selection guide, and documentation files of processor manuals, CrossCore Embedded Studio software manuals, and hardware tools manuals for the following processor families: Blackfin, SHARC, TigerSHARC, ADSP-218x, and ADSP-219x.

To order the technical library CD, go to <http://www.analog.com/processors/manuals>, navigate to the manuals page for your processor, click the request CD check mark, and fill out the order form.

Data sheets, which can be downloaded from the Analog Devices Web site, change rapidly, and therefore are not included on the technical library CD. Technical manuals change periodically. Check the Web site for the latest manual revisions and associated documentation errata.

**NOTE:** The technical library CD is no longer available. This media will be replaced with another form of publicly available media in the near future.

## Notation Conventions

Text conventions used in this manual are identified and described as follows. Additional conventions, which apply only to specific chapters, may appear throughout this document.

| Example                   | Description                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Close command (File menu) | Titles in reference sections indicate the location of an item within the CrossCore Embedded Studio IDE's menu system (for example, the <b>Close</b> command appears on the <b>File</b> menu). |

| Example                                      | Description                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {this   that}                                | Alternative required items in syntax descriptions appear within curly brackets and separated by vertical bars; read the example as <i>this</i> or <i>that</i> . One or the other is required.                                                                                                                                                      |
| [this   that]                                | Optional items in syntax descriptions appear within brackets and separated by vertical bars; read the example as an optional <i>this</i> or <i>that</i> .                                                                                                                                                                                          |
| [this,]                                      | Optional item lists in syntax descriptions appear within brackets delimited by commas and terminated with an ellipse; read the example as an optional comma-separated list of <i>this</i> .                                                                                                                                                        |
| .SECTION                                     | Commands, directives, keywords, and feature names are in text with <i>letter gothic font</i> .                                                                                                                                                                                                                                                     |

# Register Diagram Conventions

Register diagrams use the following conventions:

- The descriptive name of the register appears at the top with the short form of the name.
- If the register is read-only (RO), write-1-to-set (W1S), or write-1-to-clear (W1C), this information appears beside the name.
- If any bits in the register do not follow the overall read/write convention, this is noted in the bit description after the bit name.
- If a bit has a short name, the short name appears first in the bit description, followed by the long name.
- The reset value appears in binary in the individual bits and in hexadecimal to the left of the register.
- Bits marked X have an unknown reset value. Consequently, the reset value of registers that contain such bits is undefined or dependent on pin values at reset.
- Shaded bits are reserved.

**NOTE:** To ensure upward compatibility with future implementations, write back the value that is read for reserved bits in a register, unless otherwise specified.

# 1 Introduction

The ADSP-BF60x processors are members of the Blackfin family of products, incorporating the Analog Devices/Intel Micro Signal Architecture (MSA). Blackfin processors combine a dual-MAC state-of-the-art signal processing engine, the advantages of a clean, orthogonal RISC-like microprocessor instruction set, and single-instruction, multiple-data (SIMD) multimedia capabilities into a single instruction-set architecture.

The processor offers high performance, as well as low static power consumption. Produced with a low-power and low-voltage design methodology, they provide world-class power management and performance.

As shown in the block diagram figure, by integrating a rich set of industry-leading system peripherals and memory, Blackfin processors are the platform of choice for next-generation applications that require RISC-like programmability, multimedia support, and leading-edge signal processing in one integrated package. These applications span a wide array of markets, from automotive systems to embedded industrial, instrumentation and power/motor control applications.

**Figure 1-1:** ADSP-BF60x Functional Block Diagram

## Blackfin Processor Core

As shown in the [ADSP-BF60x Functional Block Diagram](#), the processor integrates two Blackfin processor cores. Each core, shown in [Blackfin Processor Core](#), contains two 16-bit multipliers, two 40-bit accumulators, two 40-bit ALUs, four video ALUs, and a 40-bit shifter. The computation units process 8-, 16-, or 32-bit data from the register file.

The compute register file contains eight 32-bit registers. When performing compute operations on 16-bit operand data, the register file operates as 16 independent 16-bit registers. All operands for compute operations come from the multiported register file and instruction constant fields.

Each MAC can perform a 16-bit by 16-bit multiply in each cycle, accumulating the results into the 40-bit accumulators. Signed and unsigned formats, rounding, and saturation are supported.

The ALUs perform a traditional set of arithmetic and logical operations on 16-bit or 32-bit data. In addition, many special instructions are included to accelerate various signal processing tasks. These include bit operations such as field extract and population count, modulo  $2^{32}$  multiply, divide primitives, saturation and rounding, and sign/exponent detection. The set of video instructions include byte alignment and packing operations, 16-bit and 8-bit adds with clipping, 8-bit average operations, and 8-bit subtract/abso-

lute value/accumulate (SAA) operations. Also provided are the compare/select and vector search instructions.

For certain instructions, two 16-bit ALU operations can be performed simultaneously on register pairs (a 16-bit high half and 16-bit low half of a compute register). If the second ALU is used, quad 16-bit operations are possible.

The 40-bit shifter can perform shifts and rotates and is used to support normalization, field extract, and field deposit instructions.

The program sequencer controls the flow of instruction execution, including instruction alignment and decoding. For program flow control, the sequencer supports PC relative and indirect conditional jumps (with static branch prediction), and subroutine calls. Hardware supports zero-overhead looping. The architecture is fully interlocked, meaning that the programmer need not manage the pipeline when executing instructions with data dependencies.

The address arithmetic unit provides two addresses for simultaneous dual fetches from memory. It contains a multiported register file consisting of four sets of 32-bit index, modify, length, and base registers (for circular buffering), and eight additional 32-bit pointer registers (for C-style indexed stack manipulation).

Blackfin processors support a modified Harvard architecture in combination with a hierarchical memory structure. Level 1 (L1) memories are those that typically operate at the full processor speed with little or no latency. At the L1 level, the instruction memory holds instructions only. The data memory holds data, and a dedicated scratchpad data memory stores stack and local variable information.

In addition, multiple L1 memory blocks are provided, offering a configurable mix of SRAM and cache. The memory management unit (MMU) provides memory protection for individual tasks that may be operating on the core and can protect system registers from unintended access.

The architecture provides three modes of operation: user mode, supervisor mode, and emulation mode. User mode has restricted access to certain system resources, thus providing a protected software environment, while supervisor mode has unrestricted access to the system and core resources.

Figure 1-2: Blackfin Processor Core

## Instruction Set Description

The Blackfin processor instruction set has been optimized so that 16-bit opcodes represent the most frequently used instructions, resulting in excellent compiled code density. Complex DSP instructions are encoded into 32-bit opcodes, representing fully featured multifunction instructions. Blackfin processors support a limited multi-issue capability, where a 32-bit instruction can be issued in parallel with two 16-bit instructions, allowing the programmer to use many of the core resources in a single instruction cycle.

The Blackfin processor family assembly language instruction set employs an algebraic syntax designed for ease of coding and readability. The instructions have been specifically tuned to provide a flexible, densely encoded instruction set that compiles to a very small final memory size. The instruction set also provides fully featured multifunction instructions that allow the programmer to use many of the processor core resources in a single instruction. Coupled with many features more often seen on micro controllers, this instruction set is very efficient when compiling C and C++ source code. In addition, the architecture supports both user (algorithm/application code) and supervisor (O/S kernel, device drivers, debuggers, ISRs) modes of operation, allowing multiple levels of access to core processor resources.

The assembly language, which takes advantage of the processor's unique architecture, offers the following advantages:

- Seamlessly integrated DSP/MCU features are optimized for both 8-bit and 16-bit operations.
- A multi-issue load/store modified-Harvard architecture, which supports two 16-bit MAC or four 8-bit ALU + two load/store + two pointer updates per cycle.
- All registers, I/O, and memory are mapped into a unified 4G byte memory space, providing a simplified programming model.
- Control of all asynchronous and synchronous events to the processor is handled by two subsystems: the Core Event Controller (CEC) and the System Event Controller (SEC).
- Micro controller features, such as arbitrary bit and bit-field manipulation, insertion, and extraction; integer operations on 8-, 16-, and 32-bit data-types; and separate user and supervisor stack pointers.
- Code density enhancements, which include intermixing of 16-bit and 32-bit instructions (no mode switching, no code segregation). Frequently used instructions are encoded in 16 bits.

**NOTE:** For more information about the Blackfin instruction set, see the *Blackfin Programming Reference*.

## Processor Safety Features

The ADSP-BF60x processor has been designed for functional safety applications. While the level of safety is mainly dominated by the system concept, the following primitives are provided by the devices to build a robust safety concept.

### Dual Core Supervision

The processor has been implemented as dual-core devices to separate critical tasks to large independency. Software models support mutual supervision of the cores in symmetrical fashion.

### Fault Management

The fault management unit is part of the system event controller (SEC). Any system event, whether a dual-bit uncorrectable ECC error, or any peripheral status interrupt, can be defined as being a "fault". Additionally, the system events can be defined as an interrupt to the cores. If defined as such, the SEC forwards the event to the fault management unit which may automatically reset the entire device for reboot, or simply toggle the SYS\_FAULT output pins to signal off-chip hardware. Optionally, the fault management unit can delay the action taken via a keyed sequence, to provide a final chance for the Blackfin cores to resolve the crisis and to prevent the fault action from being taken.

## System Protection

All system resources and L2 memory banks can be controlled by either the processor cores, memory-to-memory DMA, or the system debug unit (SDU). A system protection unit (SPU) enables write accesses to specific resources that are locked to any of four masters: Core 0, Core 1, Memory DMA, and the System Debug Unit. System protection is enabled in greater granularity for some modules (L2, SEC and GPIO controllers) through a *global lock* concept.

## Bandwidth Monitor

All DMA channels that operate in memory-to-memory mode (Memory DMA, PVP Memory Pipe DMA, PIXC DMA) are equipped with a bandwidth monitor mechanism. They can signal a system event or fault when transactions tend to starve because system buses are fully loaded with higher-priority traffic.

## Private (to each Core) Memory

The L1 memory system is the highest-performance memory available to the Blackfin processor cores.

Each core has its own private L1 memory. The modified Harvard architecture supports two concurrent 32-bit data accesses along with an instruction fetch at full processor speed which provides high bandwidth processor performance. Two separate 64K-byte of data memory blocks partner with an 80K-byte memory block for instruction storage. Each block is multi banked for efficient data exchange through DMA and can be configured as SRAM. Alternatively, 16K bytes of each block can be configured in L1 cache mode. The four-way set-associative instruction cache and the 2 two-way set-associative data caches greatly accelerate memory access performance, especially when accessing external memories.

The L1 memory domain also features a 4K-byte scratchpad SRAM block which is ideal for storing local variables and the software stack. All L1 memory is protected by a multi-parity bit concept, regardless of whether the memory is operating in SRAM or cache mode.

## Shared (by both Cores) Memory

Outside of the L1 domain, L2 and L3 memories are arranged using a Von Neumann topology. The L2 memory domain is a unified instruction and data memory and can hold any mixture of code and data required by the system design. The L2 memory domain is accessible by both Blackfin cores through a dedicated 64-bit interface. It operates at half the frequency of the cores. The processor features 256K bytes of L2 SRAM which is ECC-protected and organized in eight banks. Individual banks can be made private to any of the cores or the DMA subsystem. There is also a 32K-byte single-bank ROM in the L2 domain. It contains boot code and safety functions.

## I/O Memory Space

The processor does not define a separate I/O space. All resources are mapped through the flat 32-bit address space. On-chip I/O devices have their control registers mapped into memory-mapped registers (MMRs) at addresses near the top of the 4G byte address space. These are separated into two smaller blocks, one which contains the control MMRs for all core functions, and the other which contains the registers needed for setup and control of the on-chip peripherals outside of the core. The MMRs are accessible only in supervisor mode and appear as reserved space to on-chip peripherals.

## Memory Protection

The Blackfin cores feature a memory protection concept, which grants data and/or instruction accesses from enabled memory regions only. A supervisor mode vs. user mode programming model supports dynamically varying access rights. Increased flexibility in memory page size options supports a simple method of static memory partitioning.

## Multi-Parity-Bit-Protected L1 Memories

In the processor's L1 memory space, whether SRAM or cache, each word is protected by multiple parity bits to detect the single event upsets that occur in all RAMs. This applies both to L1 instruction and data memory spaces.

## ECC-Protected L2 Memory

Error correcting codes (ECC) are used to correct single event upsets. The L2 memory is protected with a Single Error Correct-Double Error Detect (SEC-DED) code. By default ECC is enabled, but it can be disabled on a per-bank basis. Single-bit errors are transparently corrected. Dual-bit errors can issue a system event or fault if enabled. ECC protection is fully transparent to the user, even if L2 memory is read or written by 8-bit or 16-bit entities.

## CRC-Protected Memories

While parity bit and ECC protection mainly protect against random soft errors in L1 and L2 memory cells, the CRC engines can be used to protect against systematic errors (pointer errors) and static content (instruction code) of L1, L2 and even L3 memories (DDR2, LPDDR). The processors feature two CRC engines which are embedded in the memory-to-memory DMA controllers. CRC check sums can be calculated or compared on the fly during memory transfers, or one or multiple memory regions can be continuously scrubbed by single DMA work unit as per DMA descriptor chain instructions. The CRC engine also protects data loaded during the boot process.

## Watchpoint Protection

The primary purpose of watchpoints and hardware breakpoints is to serve emulator needs. When enabled, they signal an emulator event whenever user-defined system resources are accessed or a core executes from user-defined addresses. Watchdog events can be configured such that they signal the events to the other Blackfin core or to the fault management unit.

## Pin Multiplexing

The processor supports a flexible multiplexing scheme that multiplexes the GPIO pins with various peripherals. A maximum of 4 peripherals plus GPIO functionality is shared by each GPIO pin. All GPIO pins have a bypass path feature - that is, when the output enable and the input enable of a GPIO pin are both active, the data signal before the pad driver is looped back to the receive path for the same GPIO pin.

## Processor Infrastructure

The [ADSP-BF60x Functional Block Diagram](#) shows a number of system control blocks. Some of these blocks provide system control operations, such as event handling and managing the memory sub-system interface. Other of these blocks provide processor core integration (infrastructure), such as bus arbitration, clock generation, and dynamic power management. The following sections provide information on the primary infrastructure components of the ADSP-BF60x processors.

## System Crossbar (SCB)

The system crossbars (SCB) appear as buses in the [ADSP-BF60x Functional Block Diagram](#). These buses constitute a switch fabric, providing concurrent data access between on-chip bus master and slave memory spaces. Each piece of fabric consists of a matrix for each of master interfaces, and each matrix has a number of slave interfaces. Each matrix with programmable round robin arbitration has a matching number of master slots. Arbitration may be programmed by writing each slot register with a corresponding slave value.

## Clock Generation

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock that runs at a frequency that is multiple times the CLKIN input clock frequency. It also generates all on-chip clocks and synchronization signals. The PCU allows the application software to control the PLL module operation.

Multiplication factors are programmed to the PLLs to define the PLLCLK frequency. Programmable values divide the PLLCLK frequency to generate the core clock (CCLK), the system clocks (SYSCLK, SCLK0 and SCLK1), the LPDDR or DDR2 clock (DCLK) and the output clock (OCLK). This is illustrated in the [Clock Relationships and Divider Values](#) figure.

Writing to the CGU control registers does not affect the behavior of the PLL immediately. Registers are first programmed with a new value, and the PLL logic executes the changes so that it transitions smoothly from the current conditions to the new ones.

The SYS\_CLKIN pin oscillations start when power is applied to the VDD\_EXT pins. The rising edge of SYS\_HWRST can be applied as soon as all voltage supplies are within specifications, and SYS\_CLKIN oscillations are stable.

A SYS\_CLKOUT output pin has programmable options to output divided-down versions of the on-chip clocks. By default, the SYS\_CLKOUT pin drives a buffered version of the SYS\_CLKIN input. Clock generation faults (for example PLL unlock) may trigger a reset by hardware.

## Crystal Oscillator (SYS\_XTAL)

The processor can be clocked by an external crystal, a sine wave input, or a buffered, shaped clock derived from an external clock oscillator. If an external clock is used, it should be a TTL compatible signal and must not be halted, changed, or operated below the specified frequency during normal operation. This signal is connected to the processor's SYS\_CLKIN pin. When an external clock is used, the SYS\_XTAL pin must be left unconnected. Alternatively, because the processor includes an on-chip oscillator circuit, an external crystal may be used.

## Clock Out/External Clock

The SYS\_CLKOUT pin can be used to output one of several different clocks used on the processor. The clocks shown in [Clock Sources and Dividers](#) can be outputs from SYS\_CLKOUT.

**Table 1-1:** Clock Sources and Dividers

| Clock Source                                                       | Divider                     |
|--------------------------------------------------------------------|-----------------------------|
| CCLK (core clock)                                                  | By 4                        |
| SYSCLK (System clock)                                              | By 2                        |
| SCLK0 (system clock for PVP, all peripherals not covered by SCLK1) | None                        |
| SCLK1 (system clock for SPORTS, SPI, ACM)                          | None                        |
| DCLK (LPDDR/DDR2 clock)                                            | By 2                        |
| OCLK (output clock)                                                | Programmable                |
| CLKBUF                                                             | None, direct from SYS_CLKIN |

## System Protection Unit (SPU)

The system protection unit (SPU) provides features that let you protect system resources from errant writes. A number of protection categories (types of registers to protect) are available.

# Dynamic Power Management (DPM)

The dynamic power management (DPM) feature of the processor lets you control the processor's core clock frequency ( $f_{CCLK}$ ) dynamically.

As shown in clock relationships and divider values figure, the processor supports four different power domains, which maximizes flexibility while maintaining compliance with industry standards and conventions. By isolating the internal logic of the processor into its own power domain, separate from other I/O, the processor can take advantage of dynamic power management without affecting the other I/O devices.

**Figure 1-3:** Clock Relationships and Divider Values

There are no sequencing requirements for the various power domains, but all domains must be powered according to the appropriate [Power Domains and Ranges](#) table for processor operating conditions; even if the feature/peripheral is not used.

**Table 1-2:** Power Domains and Ranges

| Power Domain       | VDD Range     |
|--------------------|---------------|
| All internal logic | $V_{DD\_INT}$ |
| DDR2/LPDDR         | $V_{DD\_DDR}$ |
| USB                | $V_{DD\_USB}$ |
| All other I/O      | $V_{DD\_EXT}$ |

The power dissipated by a processor is largely a function of its clock frequency and the square of the operating voltage. For example, reducing the clock frequency by 25% results in a 25% reduction in dynamic power dissipation.

## Core Timers

Each processor core has its own dedicated timer. The core timer is clocked by the internal processor clock and is typically used as a system tick clock for generating periodic operating system interrupts.

## Event Handling

The processor provides event handling that supports both nesting and prioritization. Nesting allows multiple event service routines to be active simultaneously. Prioritization ensures that servicing of a higher-priority event takes precedence over servicing of a lower-priority event. The processor provides support for five different types of events:

- Emulation - An emulation event causes the processor to enter emulation mode, allowing command and control of the processor via the JTAG interface.
- Reset - This event resets the processor.
- Non maskable Interrupt (NMI) - The NMI event can be generated either by the software watchdog timer, by the NMI input signal to the processor, or by software. The NMI event is frequently used as a power-down indicator to initiate an orderly shutdown of the system.
- Exceptions - Events that occur synchronously to program flow (in other words, the exception is taken before the instruction is allowed to complete). Conditions such as data alignment violations and undefined instructions cause exceptions.
- Interrupts - Events that occur asynchronously to program flow. They are caused by input signals, timers, and other peripherals, as well as by an explicit software instruction.

The [ADSP-BF60x Functional Block Diagram](#) shows a number of system control blocks. Some of these blocks provide system control operations, such as event handling and managing the memory sub-system interface. The following sections provide information on the event handling components of the ADSP-BF60x processors.

### Core Event Controller (CEC)

The CEC supports nine general-purpose interrupts (IVG15-7), in addition to the dedicated interrupt and exception events. Of these general-purpose interrupts, the two lowest-priority interrupts (IVG15-14) are recommended to be reserved for software interrupt handlers. For more information about general-purpose interrupts, see the *Blackfin Processor Programmer's Reference*.

### System Event Controller (SEC)

The SEC manages the enabling, prioritization, and routing of events from each system interrupt or fault source. Additionally, it provides notification and identification of the highest priority active system interrupt request to each core and routes system fault sources to its integrated fault management unit.

## Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger masters (generators of triggers) to trigger slaves (receivers of triggers). Slave endpoints can be configured to respond to triggers in various ways. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

## Pin Interrupts

Every port pin on the processor can request interrupts in either an edge-sensitive or a level-sensitive manner with programmable polarity. Interrupt functionality is decoupled from GPIO operation. Six system-level interrupt channels (PINT0-5) are reserved for this purpose. Each of these interrupt channels can manage up to 32 interrupt pins. The assignment from pin to interrupt is not performed on a pin-by-pin basis. Rather, groups of eight pins (half ports) can be flexibly assigned to interrupt channels.

Every pin interrupt channel features a special set of 32-bit memory-mapped registers that enable half-port assignment and interrupt management. This includes masking, identification, and clearing of requests. These registers also enable access to the respective pin states and use of the interrupt latches, regardless of whether the interrupt is masked or not. Most control registers feature multiple MMR address entries to write-one-to-set or write-one-to-clear them individually.

## Memory Architecture

The ADSP-BF60x processor views memory as a single unified 4G byte address space, using 32-bit addresses. All resources, including internal memory, external memory, and I/O control registers, occupy separate sections of this common address space. The memory portions of this address space are arranged in a hierarchical structure to provide a good cost/performance balance of some very fast, low-latency core-accessible memory as cache or SRAM, and larger, lower-cost and performance interface-accessible memory systems.

The processor block diagram shows a number of system control blocks. Some of these blocks provide system control operations, such as event handling and managing the memory sub-system interface. The following sections provide information on managing the memory sub-system interface of the ADSP-BF60x processors.

See the product specific data sheet for the proper external and internal memory configurations.

## Static Memory Controller (SMC)

The static memory controller (SMC) is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory.

The SMC can be programmed to control up to four banks of external memories or memory-mapped devices, with very flexible timing parameters. Each bank occupies a 64M byte segment regardless of the size of the device used, so that these banks are only contiguous if each is fully populated with 64M bytes of memory.

SMC acts as an SCB slave and accesses to SMC are arbitrated by the processor SCB interconnect fabric. On the chip boundary, the SMC is connected to a 25-bit external memory address bus, a 16-bit data bus and memory control signal pins (read, write) including four chip selects via the chip pads. The SMC can support 64 MB of external memory connected to four different banks—each bank is controlled by the chip select signal.

## L2 Memory Controller

The L2 memory controller is an SCB slave with multiple SCB ports that access banks of RAM and/or ROM. These interfaces and the memory subsystem run at the  $L2CLK$  frequency. The L2 memory controller also has a bus interface to provide access to the L2 controller's control and status registers. Each bank of L2 memory is protected by ECC (error correction and control) logic which ensures that single bit errors can be corrected and multi-bit errors can be detected. For each 32KB bank, a 4Kx14 bits ECC RAM stores the parity bits.

## Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glue-less interface between DDR2/LPDDR SDRAMs and the system crossbar interface (SCB) on-chip interconnect. This controller supports JESD79-2E compatible double data rate (DDR2) SDRAM and JESD209A low power DDR (LPDDR) SDRAM devices. The DMC enables execution of instructions from (as well as transfer of data to-and-from) external DDR2 SDRAM and external LPDDR SDRAM.

The DMC supports access to the external memory by core and DMA accesses. The external memory address space is divided in to four banks.

The DMC is partitioned in a manner that allows configuration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the protocol controller. An access and operation re-ordering mechanism is incorporated as an efficiency controller. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient slave implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC controller can be accessed using the MMR access bus.

## Cyclic Redundancy Check (CRC)

The cyclic redundancy check (CRC) peripheral performs the CRC operation of the block of data that is presented to the peripheral. The peripheral provides a means to periodically verify the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects.

The CRC is a hardware module based on a CRC32 engine that computes the CRC value of the 32-bit data words presented to it. Data is provided by the source channel of the memory-to-memory DMA (in memory scan mode) and is optionally forwarded to the destination channel (memory transfer mode). The main features of the CRC peripheral are:

- Memory scan, memory transfer, data verify, and data fill modes
- User-programmable CRC32 polynomial
- Bit/byte mirroring option (endianness)
- Fault/error interrupt mechanisms
- 1D and 2D fill block to initialize array with constants.
- 32-bit CRC signature of a block of a memory or MMR block.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature and if the two fail to match, the peripheral generates an error.

Data may be provided by the source channel of the memory-to-memory DMA channels and optionally forwarded to memory via the destination DMA channel. Alternatively, the peripheral also supports data presented by core write transactions.

The CRC peripheral implements a reduced table-lookup algorithm to compute the signature of the data. A programmable 32-bit CRC polynomial is used to automatically generate the lookup table (LUT) contents.

Additional CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

The two CRC protection modules allow system software to periodically calculate the signature of code and/or data in memory, the content of memory-mapped registers, or communication message objects. Dedicated hardware circuitry compares the signature with pre calculated values and triggers appropriate fault events.

## Direct Memory Access (DMA)

The direct memory access (DMA) channels are dispersed throughout the infrastructure and may be clustered together over SCBs, sharing a single interface with the main system crossbar.

The processor uses DMA to transfer data within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA controller carries out the data transfers independent of processor activity.

The DMA channels can perform transfers between memory and a peripheral or between one memory and another memory. Two DMA channels are required for memory to memory DMA transfers (MDMA). One channel is the source channel, and the second, the destination channel.

The DMA channel does not connect external memories and devices directly. Rather, data is passed through an external memory interface port. Any kind of device that is supported by the external memory interface can also be accessed by DMA operation. This is typically flash memory, SRAM, DDR SDRAM, FIFOs, or memory-mapped peripheral devices.

All DMAs can transport data to and from all on-chip and off-chip memories. Programs can use two types of DMA transfers, descriptor-based or register-based. Register-based DMA allows the processor to directly program DMA control registers to initiate a DMA transfer. On completion, the control registers may be automatically updated with their original setup values for continuous transfer. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based DMA transfers allow multiple DMA sequences to be chained together and a DMA channel can be programmed to automatically set up and start another DMA transfer after the current sequence completes.

The DMA controller supports the following DMA operations.

- A single linear buffer that stops on completion.
- A linear buffer with negative, positive or zero stride length.
- A circular, auto-refreshing buffer that interrupts when each buffer becomes full.
- A similar buffer that interrupts on fractional buffers (for example, 1/2, 1/4).
- 1D DMA - uses a set of identical ping-pong buffers defined by a linked ring of two-word descriptor sets, each containing a link pointer and an address.
- 1D DMA - uses a linked list of 4 word descriptor sets containing a link pointer, an address, a length, and a configuration.
- 2D DMA - uses an array of one-word descriptor sets, specifying only the base DMA address.
- 2D DMA - uses a linked list of multi-word descriptor sets, specifying everything.

## On Chip Peripherals

The processor contains a set of on chip peripherals connected to the core over several high-bandwidth buses. These system interface peripherals provide flexibility in system configuration and system performance (see the [ADSP-BF60x Functional Block Diagram](#)). The following sections describe the on chip peripherals that provide the system interface.

## General-Purpose I/O (GPIO)

The general-purpose I/O (GPIO) ports provide the following functions.

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupts

The GPIO port pins can be individually controlled using the port control, status, and interrupt registers. These registers let you:

- Specify the direction of each individual GPIO pin as input or output
- Use the "write one to modify" mechanism to modify any combination of individual GPIO pins in a single instruction, without affecting the level of any other GPIO pins.
- Treat each individual GPIO pin as an interrupt to the processor; GPIO pins defined as inputs can be configured to generate hardware interrupts, while output pins can be triggered by software interrupts
- Specify whether individual pins are level- or edge-sensitive and specify (if edge-sensitive) whether just the rising edge or both the rising and falling edges of the signal are significant

## General-Purpose Timers

The general-purpose timer provides eight general-purpose programmable timers. Each timer has an external pin that can be configured either as a pulse width modulator (PWM) or timer output, as an input to clock the timer, or as a mechanism for measuring pulse widths and periods of external events. These timers can be synchronized to an external clock input on the TMR<sub>x</sub> pins, an external clock TMRCLK input pin, or to the internal SCLK0.

Additionally, a variety of interrupts can be generated upon completion of timer events. Moreover, GP timers can act both as trigger masters and trigger slaves.

The timer units can be used in conjunction with the UARTs and the CAN controller to measure the width of the pulses in the data stream to provide a software auto-baud detect function for the respective serial channels.

## Watchdog Timers

Each core includes a 32-bit timer, which may be used to implement a software watchdog function. A software watchdog can improve system availability by forcing the processor to a known state, via generation of a hardware reset, non maskable interrupt (NMI), or general-purpose interrupt, if the timer expires before being reset by software. The programmer initializes the count value of the timer, enables the appropriate interrupt, then enables the timer. Thereafter, the software must reload the counter before it counts to zero from the programmed value. This protects the system from remaining in an unknown state where

software, which would normally reset the timer, has stopped running due to an external noise condition or software error.

After a reset, software can determine if the watchdog was the source of the hardware reset by interrogating a status bit in the timer control register, which is set only upon a watchdog generated reset.

## General-Purpose Counters

A 32-bit counter is provided that can operate in general-purpose up/down count modes and can sense 2-bit quadrature or binary codes as typically emitted by industrial drives or manual thumbwheels. Count direction is either controlled by a level-sensitive input pin or by two edge detectors.

A third counter input can provide flexible zero marker support and can alternatively be used to input the push-button signal of thumb wheels. All three pins have a programmable debouncing circuit.

Internal signals forwarded to each general-purpose timer enable these timers to measure the intervals between count events. Boundary registers enable auto-zero operation or simple system warning by interrupts when programmable count values are exceeded.

Using this feature, you can convert pulses from incremental position encoders into data that is representative of the actual position by integrating (counting) pulses on one or two inputs. Because integration provides relative position, some devices also feature a zero position input (zero marker) that can be used to establish a reference point to verify that the acquired position does not drift over time. The incremental position information also can be used to determine speed, if the time intervals are measured. The GP counter provides flexible ways to establish position information. When used in conjunction with the GP timer block, the GP counter lets you acquire coherent position and time-stamp information that enables speed calculation.

## Pulsewidth Modulator (PWM)

Each pulsewidth modulator (PWM) block integrates a flexible and programmable 3-phase PWM waveform generator that can be programmed to generate the required switching patterns to drive a 3-phase voltage source inverter for ac induction motor (ACIM) or permanent magnet synchronous motor (PMSM) control. In addition, the PWM block contains special functions that considerably simplify the generation of the required PWM switching patterns for control of the electronically commutated motor (ECM) or brushless dc motor (BDCM). Software can enable a special mode for switched reluctance motors (SRM). The two 3-phase PWM generation units each feature:

- 16-bit center-based PWM generation unit
- Programmable PWM pulse width
- Single/double update modes
- Programmable dead time and switching frequency
- Twos-complement implementation which permits smooth transition to full ON and full OFF states

- Dedicated asynchronous PWM shutdown signal

The eight PWM output signals (per PWM unit) consist of four high-side drive signals and four low-side drive signals. The polarity of a generated PWM signal can be set with software, so that either active HI or active LO PWM patterns can be produced.

Pulses synchronous to the switching frequency can be generated internally and output on the PWM\_SYNC pin. The PWM unit can also accept externally generated synchronization pulses through PWM\_SYNC.

Each PWM unit features a dedicated asynchronous shutdown pin which (when brought low) instantaneously places all six PWM outputs in the OFF state.

## Universal Asynchronous Receiver/Transmitter (UART)

The processors provide two full-duplex universal asynchronous receiver/transmitter (UART) ports, which are fully compatible with PC-standard UARTs. Each UART port provides a simplified UART interface to other peripherals or hosts, supporting full-duplex, DMA-supported, asynchronous transfers of serial data.

A UART port includes support for five to eight data bits, and none, even, or odd parity. Optionally, an additional address bit can be transferred to interrupt only addressed nodes in multi-drop bus (MDB) systems. A frame is terminated by one, one and a half, two or two and a half stop bits. The UARTs also include interrupt-handling hardware. Interrupts can be generated from multiple events.

The UARTs are logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually require external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UARTs meet the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UARTs meet the full-duplex MDB/ICP v2.0 protocol.

Partial modem status and control functionality is supported by the UART module to allow for hardware flow control. The UART ports support automatic hardware flow control through the Clear To Send (CTS) input and Request To Send (RTS) output with programmable assertion FIFO levels.

To help support the Local Interconnect Network (LIN) protocols, a special command causes the transmitter to queue a break command of programmable bit length into the transmit buffer. Similarly, the number of stop bits can be extended by a programmable inter-frame space.

The capabilities of the UARTs are further extended with support for the Infrared Data Association (IrDA) serial infrared physical layer link specification (SIR) protocol.

The UARTs are DMA-capable peripherals with support for separate transmit and receive DMA master channels. They can be used in either DMA or programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention as the DMA engine itself moves the data. Each UART has its own separate transmit and receive DMA channels.

One of the peripheral timers can be used to provide a hardware-assisted auto-baud detection mechanism for use with the UART. The timers are external to the UART.

## 2-Wire Interface (TWI)

The processors include a 2-wire interface (TWI), providing a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I<sup>2</sup>C bus standard. The TWI module offers the capabilities of simultaneous master and slave operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface utilizes two pins for transferring clock (TWI\_SCL) and data (TWI\_SDA) and supports the protocol at speeds up to 400k bits/sec. The TWI interface pins are compatible with 5 V logic levels.

Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

To preserve processor bandwidth, the TWI module can be set up with transfer initiated interrupts only to service FIFO buffer data reads and writes. Protocol related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I<sup>2</sup>C bus protocol.

## Controller Area Network (CAN)

The processor includes a controller area network (CAN) module, which implements the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is well suited for control applications due to its capability to communicate reliably over a network. This is because the protocol incorporates CRC checking, message error tracking, and fault node confinement.

**NOTE:** This document assumes reader familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN Specification from Robert Bosch GmbH.

The CAN module provides the following features:

- 32 mailboxes (8 receive only, 8 transmit only, 16 configurable for receive or transmit)
- Dedicated acceptance masks for each mailbox
- Additional data filtering on first two bytes.
- Support for both the standard (11-bit) and extended (29-bit) identifier (ID) message formats
- Support for remote frames
- Active or passive network support
- CAN wakeup from hibernation mode (lowest static power consumption mode)
- Interrupts, including: TX complete, RX complete, error and global

**NOTE:** An additional crystal is not required to supply the CAN clock, as the CAN clock is derived from a system clock through a programmable divider.

## Universal Serial Bus (USB)

The processor's universal serial bus (USB) module is a USB 2.0 compliant, dual-role device controller. This interface provides a low-cost connectivity solution for the growing adoption of this bus standard in industrial applications and consumer mobile devices, such as cell phones, digital still cameras, and MP3 players. The USB module lets these devices transfer data using a point-to-point USB connection without the need for a PC host.

The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the on-the-go (OTG) supplement<sup>1</sup> to the USB 2.0 Specification<sup>2</sup>. In host mode, the USB module supports transfers at high-speed (480Mbps), full-speed (12Mbps), and low-speed (1.5Mbps) rates. Peripheral mode supports the high- and full-speed transfer rates.

The USB controller uses a peripheral bus slave interface to access its control and status registers as well as read and write to the endpoint packet buffers. Data is transferred to and from the USB controller through any of the transmit and receive endpoint FIFOs. A DMA bus master interface provides numerous DMA channels to provide a more efficient means of transferring large amounts of data between the controller and the Blackfin processor's memory map.

The USB clock (USB\_CLKIN) is provided through a dedicated external crystal or crystal oscillator. Using an included phase locked loop with programmable multipliers, the USB on-the-go dual-role device controller generates the necessary internal clocking frequency for USB.

## Ethernet Media Access Controller (MAC)

The processor can directly connect to a network by way of an embedded fast Ethernet media access controller (MAC) that supports both 10-BaseT (10M bits/sec) and 100-BaseT (100M bits/sec) operation. The 10/100 Ethernet MAC peripheral on the processor is fully compliant to the IEEE 802.3-2002 standard and it provides programmable features designed to minimize supervision, bus use, or message processing by the rest of the processor system.

Some standard Ethernet MAC features are:

- Support and RMI protocols for external PHYs
- Full duplex and half duplex modes
- Media access management (in half-duplex operation)
- Flow control
- Station management: generation of MDC/MDIO frames for read-write access to PHY registers

---

1. On-The-Go Supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF

2. Universal Serial Bus Specification 2.0

Some advanced Ethernet MAC features are:

- Automatic checksum computation of IP header and IP payload fields of Rx frames
- Independent 32-bit descriptor-driven receive and transmit DMA channels
- Frame status delivery to memory through DMA, including frame completion semaphores for efficient buffer queue management in software
- Tx DMA support for separate descriptors for MAC header and payload to eliminate buffer copy operations
- Convenient frame alignment modes
- 47 MAC management statistics counters with selectable clear-on-read behavior and programmable interrupts on half maximum value
- Advanced power management
- Magic packet detection and wakeup frame filtering
- Support for 802.3Q tagged VLAN frames
- Programmable MDC clock rate and preamble suppression

The Ethernet MAC includes support for the IEEE 1588 standard. This standard is a precision clock synchronization protocol for networked measurement and control systems. The processor includes hardware support for IEEE 1588 with an integrated precision time protocol synchronization engine (PTP\_TSYNC). This engine provides hardware assisted time stamping to improve the accuracy of clock synchronization between PTP nodes.

The main IEEE 1588 standard features of the engine are:

- Support for both IEEE 1588-2002 and IEEE 1588-2008 protocol standards
- Hardware assisted time stamping capable of up to 12.5 ns resolution
- Lock adjustment
- Automatic detection of IPv4 and IPv6 packets, as well as PTP messages
- Multiple input clock sources (SCLK0, RMII clock, external clock)
- Programmable pulse per second (PPS) output
- Auxiliary snapshot to time stamp external events

## Removable Storage Interface (RSI)

The removable storage interface (RSI) controller acts as the host interface for multimedia cards (MMC), secure digital memory cards (SD), secure digital input/output cards (SDIO), and CE-ATA hard disk drives. The following list describes the main features of the RSI controller.

- Support for a single MMC, SD memory, SDIO card or CE-ATA hard disk drive
- Support for 1-bit and 4-bit SD modes
- Support for 1-bit, 4-bit, and 8-bit MMC modes
- Support for 4-bit and 8-bit CE-ATA hard disk drives
- Support for eMMC 4.3 embedded NAND flash devices
- A ten-signal external interface with clock, command, and up to eight data lines
- Card interface clock generation from SCLK0
- SDIO interrupt and read wait features
- CE-ATA command completion signal recognition and disable

## Serial Peripheral Interface (SPI)

The processors have two serial peripheral interface (SPI) compatible ports that allow the processor to communicate with multiple SPI compatible devices.

In its simplest mode, the SPI interface uses three pins for transferring data: two data pins (Master Output-Slave Input, MOSI, and Master Input-Slave Output, MISO) and a clock pin (serial clock, SCK). An SPI chip select input pin (SPISS) lets other SPI devices select the processor, and seven SPI chip select output pins (SPISEL7-1) let the processor select other SPI devices. The SPI select pins are reconfigured general-purpose I/O pins. Using these pins, the SPI port provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi master environments.

The SPI port's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams.

## Serial Port (SPORT)

The processor includes three synchronous serial ports (SPORTs) that provide an inexpensive interface to a wide variety of digital and mixed-signal peripheral devices such as the AD183x family of audio CODECs, ADCs, and DACs from Analog Devices. The SPORTs consist of two data lines, a clock, and frame sync. The data lines can be programmed to either transmit or receive and each data line has a dedicated DMA channel.

SPORT data can be automatically transferred to and from on-chip memory/external memory over dedicated DMA channels. Each of the SPORTs can work in conjunction with another SPORT to provide TDM support. In this configuration, one SPORT provides two transmit signals while the other SPORT provides the two receive signals. The frame sync and clock are shared.

Serial ports may operate in any of the following modes:

- Standard DSP serial mode
- Multichannel (TDM) mode
- I<sup>2</sup>S mode
- Packed I<sup>2</sup>S mode
- Left-justified mode

## ADC Control Module (ACM)

The processor includes an ADC control module (ACM) that provides an interface that synchronizes the controls between the processor and an analog-to-digital converter (ADC). The analog-to-digital conversions are initiated by the processor, based on external or internal events.

The ACM permits flexible scheduling of sampling instants and provides precise sampling signals to the ADC.

The ADC, ACM, and SPORT Connections diagram shows how to connect an external ADC to the ACM and one of the three SPORTs.

The ACM synchronizes the ADC conversion process, generating the ADC controls, the ADC conversion start signal, and other signals. The actual data acquisition from the ADC is done by a peripheral, such as a SPORT or a SPI.

The processor interfaces directly to many ADCs without any glue logic required.

**Figure 1-4:** ADC, ACM, and SPORT Connections

## Link Port (LP)

Four DMA-enabled, 8-bit-wide link ports can connect to the link ports of other Blackfin processors or other link-enabled processors. Link ports are bi-directional ports with eight data lines, an acknowledge line, and a clock line.

## Video Sub-System and Pixel Pipeline (PxP)

The processor's video sub-system provides a connectivity matrix that interconnects the video related peripherals. The pixel pipeline (PxP) protocol is used for data transfer among these video peripherals.

- Three enhanced parallel peripheral interface (PPI) ports
- The pixel compositor (PIXC)
- The pipelined vision processor (PVP)
- The video interconnect (bus) and pixel pipeline (PxP)
- 18 DMA channels

The PPIs can operate in video input and video output modes, and also support several general-purpose modes of operation. These parallel ports are aware of video frame synchronization, blanking concepts and color formats. They can receive up to 16-bit video data directly from video sensors (cameras) and also directly control displays on the output.

The PIXC supports color space conversion and alpha blending for video overlays.

The PVP provides a framework for various vision processing elements, which are targeting mainly edge and object detection strategies.

The video interconnect is a local, distributed bus system, which interconnects the PPI ports, the PIXC, and the PVP.

## Pipelined Vision Processor (PVP)

The pipelined vision processor (PVP) provides hardware implementation of signal and image processing algorithms that are required for co-processing and pre-processing of monochrome video frames in ADAS applications, robotic systems, and other machine applications.

The PVP works in conjunction with the Blackfin cores. It is optimized for convolution and wavelet based object detection and classification, and tracking and verification algorithms. The PVP has the following processing blocks.

- Four 5x5 16-bit convolution blocks optionally followed by downscaling
- A 16-bit cartesian-to-polar coordinate conversion block
- A pixel edge classifier that supports 1st and 2nd derivative modes
- An arithmetic unit with 32-bit addition, multiply and divide
- A 32-bit threshold block with 16 thresholds, a histogram, and run-length encoding
- Two 32-bit integral blocks that support regular and diagonal integrals
- An up- and down-scaling unit with independent scaling ratios for horizontal and vertical components
- Input and output formatters for compatibility with many data formats, including Bayer input format

The PVP can form a pipe of all the constituent algorithmic modules and is dynamically configurable to form different pipeline structures.

The PVP supports the simultaneous processing of up to four data streams. The memory pipe stream operates on data received by DMA from any L1, L2, or L3 memory. The three camera pipe streams operate on a common input received directly from any of the three PPI inputs. Optionally, the PIXC can convert color data received by the PPI and forward luma values to the PVP's monochrome engine. Each stream has a dedicated DMA output. This preprocessing concept ensures careful use of available power and bandwidth budgets and frees up the processor cores for other tasks.

The PVP provides for direct core MMR access to all control/status registers. Two hardware interrupts interface to the system event controller. For optimal performance, the PVP allows register programming through its control DMA interface, as well as outputting selected status registers through the status DMA interface. This mechanism enables the PVP to automatically process job lists completely independent of the Blackfin cores.

## Parallel Peripheral Interface (PPI)

The enhanced parallel peripheral interface (PPI) is a half-duplex, bidirectional port with a dedicated clock pin and three frame sync (FS) pins. It can support direct connections to active TFT LCD, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general-purpose peripherals. Each PPI has a DMA channel associated with it. Moreover, in some modes, a PPI may use an additional DMA channel.

The processor provides up to three parallel peripheral interfaces (PPIs), supporting data widths up to 24 bits. The PPI supports direct connection to TFT LCD panels, parallel analog-to-digital and digital-to-analog converters, video encoders and decoders, image sensor modules and other general-purpose peripherals.

The following features are supported in the PPI module:

- Programmable data length: 8 bits, 10 bits, 12 bits, 14 bits, 16 bits, 18 bits, and 24 bits per clock.
- Various framed, non-framed, and general-purpose operating modes. Frame syncs can be generated internally or can be supplied by an external device.
- ITU-656 status word error detection and correction for ITU-656 receive modes and ITU-656 preamble and status word decode.
- Optional packing and unpacking of data to/from 32 bits from/to 8 bits, 16 bits and 24 bits. If packing/unpacking is enabled, endianness can be configured to change the order of packing/unpacking of bytes/words.
- RGB888 can be converted to RGB666 or RGB565 for transmit modes.
- Various de-interleaving/interleaving modes for receiving/transmitting 4:2:2 YCrCb data.
- Configurable LCD data enable (DEN) output available on Frame Sync 3.

## Pixel Compositor (PIXC)

The pixel compositor (PIXC) provides data overlay, transparent color, and color space conversion support. This allows for supporting different video outputs including active (TFT) flat-panel digital color/monochrome LCD displays and analog NTSC/PAL. The color space conversion and text/graphic overlay capabilities, along with visual effect controls, such as transparency control, shorten the processing time on an image data stream, reduce power consumption and save system board space by removing the need for external glue logic.

The PIXC is used to combine and format the data streams required by a wide variety of digital LCD panels and NTSC/PAL analog encoders. It provides all the control needed to allow two data streams from two separate data buffers to be combined and converted into appropriate formats for both LCD panels and video output displays. The main image buffer provides the basic background image presented in the data stream. The overlay image buffer allows the user to add foreground text and graphics on top of the main

image data stream. This feature is useful for printing additional graphical or textual information on the screen, such as symbols or a menu, while showing the main image in the background.

Overlay is an option and can be enabled or disabled. If it is disabled, the blender/compositor is bypassed and the data stream from the main image buffer goes directly to memory with optional color space conversion.

Transparent color is just a special case of blending, masking off the blend operation on a pixel-by-pixel basis. In other words, the overlay region consists of sub-regions in any particular color convenient to the programmer and then, if the color data for a given overlay pixel matches the specified transparent color, the overlay function is masked for that pixel and its data is taken solely from the main image buffer, which is stored in memory in either YUV 4:2:2 interleaved format or RGB888 format

Regardless of the data format or buffer structure, each color element is 8 bits wide. If overlay is enabled, a graphics/text overlay data buffer is defined in memory. The color space converter can switch positions among any of the three locations; it can be in the image data path, the overlay data path, or after the blender. The exact position of the color space converter depends on the input and output data formats.

Since the end display may be a TV (NTSC/PAL) or an LCD panel, and since the image/overlay input buffers may be in either RGB888 or YUV4:2:2 format, a color space conversion may be needed. The color space conversion is selected according to the input data stream format of the PIXC. A YUV-to-RGB format conversion is necessary if the end display is an LCD and if either of the PIXC input data streams is in YUV 4:2:2 format. Similarly, an RGB-to-YUV format conversion is necessary if the end display is a TV and if either of the PIXC input data streams is in RGB888 format.

If the final display device is an LCD, the output RGB data stream is always packed in RGB 8-bit serial format when transferring back to memory. Similarly, if the final display device is a TV, the YUV data stream is always packed in YUV 4:2:2 interleaved format when transferring back to memory.

## Reset Control Unit (RCU)

Reset is the initial state of the whole processor or one of the cores and is the result of a hardware or software triggered event. In this state, all control registers are set to their default values and functional units are idle. Exiting a full system reset starts with Core-0 only being ready to boot. Exiting a Core-n only reset starts with this Core-n being ready to boot.

The reset control unit (RCU) controls how all the functional units enter and exit reset. Differences in functional requirements and clocking constraints define how reset signals are generated. Programs must guarantee that none of the reset functions puts the system into an undefined state or causes resources to stall. This is particularly important when only one of the cores is reset (programs must ensure that there is no pending system activity involving the core that is being reset).

From a system perspective reset is defined by both the reset target and the reset source as described below.

Target defined:

- Hardware Reset - All functional units are set to their default states without exception. History is lost.
- System Reset - All functional units except the RCU are set to their default states.
- Core-n only Reset - Affects Core-n only. The system software should guarantee that the core in reset state is not accessed by any bus master.

Source defined:

- Hardware Reset - The `SYS_HWRST` input signal is asserted active (pulled down).
- System Reset - May be triggered by software (writing to the `RCU_CTL` register) or by another functional unit such as the dynamic power management (DPM) unit (Hibernate) or any of the system event controller (SEC), trigger routing unit (TRU), or emulator. inputs.
- Core-n-only reset - Triggered by software.
- Trigger request (peripheral).

## Booting

The processor has several mechanisms for automatically loading internal and external memory after a reset. The boot mode is defined by the `SYS_BMODE` input pins dedicated for this purpose. There are two categories of boot modes. In master boot modes, the processor actively loads data from parallel or serial memories. In slave boot modes, the processor receives data from external host devices.

The boot modes are shown in the [SYS\\_BMODE Selections and Boot Modes](#) table. These modes are implemented by the `SYS_BMODE` bits of the reset configuration register and are sampled during power-on resets and software-initiated resets.

**Table 1-3:** SYS\_BMODE Selections and Boot Modes

| SYS_BMODE Setting | Boot Mode    |
|-------------------|--------------|
| 000               | No boot/Idle |
| 001               | Flash        |
| 010               | RSI0 Master  |
| 011               | SPI0 Master  |
| 100               | SPI0 Slave   |
| 101               | Reserved     |
| 110               | LP0 Slave    |
| 111               | UART0 Slave  |

## System Design

TBD.

## System Debug Unit

The System Debug Unit (SDU) provides IEEE-1149.1 support through its JTAG interface. In addition to traditional JTAG features, present in legacy Blackfin products, the SDU adds more features for debugging the chip without halting the core processors.

## System Watchpoint Unit

The System Watchpoint Unit (SWU) is a single module which connects to a single system bus and provides for transaction monitoring. One SWU is attached to the bus going to each system slave. The SWU provides ports for all system bus address channel signals. Each SWU contains four match groups of registers with associated hardware. These four SWU match groups operate independently, but share common event (interrupt, trigger, etc.) outputs.

## 2 System Crossbars (SCB)

The System Crossbars (SCB) are the fundamental building blocks of a switch-fabric style system interconnect. The SCBs connect system masters to system slaves and provide concurrent data transfer between multiple masters and multiple slaves. A hierarchical model built from multiple SCBs provides a power and area efficient system interconnect that satisfies the performance and flexibility requirements of a specific system.

### SCB Features

- Highly efficient, pipelined transfer protocol for sustained throughput
- Full-duplex operation for flexibility and reduced latency
- Concurrent transfer support to allow multiple masters to access slaves simultaneously
- Support for protection model (privileged/secure) built into the interconnect
- Programmable arbitration model for bandwidth and latency management

### SCB Functional Description

The following sections provide a functional description of the SCB:

- [SCB Register List](#)
- [SCB Definitions](#)
- [SCB Block Diagram](#)

### SCB Register List

The system cross bar (SCB), which is often referred to as the system interconnect fabric, is a collection of interconnection units connecting system masters to slave memory spaces. Each unit in the fabric consists of a matrix of master interfaces (MIn). Each of these matrices has a number of slave interfaces (SIn). The SCBs (units in the fabric) with multiple SI for each MI have programmable round-robin arbitration to manage access to slots. A set of registers govern SCB operations. For more information on SCB functionality, see the SCB register descriptions.

Table 2-1: SCB Module Registers

| Name        | Description                                           |
|-------------|-------------------------------------------------------|
| SCB_ARBRn   | Arbitration Read Channel Master Interface n Register  |
| SCB_ARBWn   | Arbitration Write Channel Master Interface n Register |
| SCB_SLAVES  | Slave Interfaces Number Register                      |
| SCB_MASTERS | Master Interfaces Number Register                     |

SCB Definitions

To make the best use of the SCB, it is useful to understand the following terms:

*MI (Master Interface)*

SCB master interface connected to system interconnect slave (e.g. L2, sMMR, SCB, etc.).

*SI (Slave Interface)*

SCB slave interface connected to system interconnect master (e.g. Core, DDE, SCB, etc.)

SCB Block Diagram

The SCB architectural model is illustrated in the following figure. A high-level overview of the SCB and associated connections to system masters and slaves is shown. A variable number of masters may be connected to a variable number of slaves in each SCB. In this example all SIs are connected to all MIs as indicated by the lines connecting them:

Figure 2-1: SCB Overview

## SCB Hierarchy Block Diagram

A system interconnect built from multiple SCBs in a hierarchical model is illustrated in the following figure. The system master node level SCBs master multiple SIs to a single MI which in turn connects to an SI of the system slave level node SCB. In this example all SIs are connected to all MIs:

**Figure 2-2:** SCB Hierarchy Overview

## ADSP-BF60x Block Diagram

The following figure shows the block diagram that is specific to the ADSP-BF60x products.

Figure 2-3: ADSP-BF60x Block Diagram.

## SCB Arbitration Tables

The SCB uses round robin arbitration to prioritize each slave's interface to masters (Master Interface) and each master's interface to slaves (Slave Interface). This section provides reference information about these interfaces.

## SCB Units, Master Interfaces, and Arbitration Types

**Table 2-2:** SCB Units, Master Interfaces, and Arbitration Types

| SCB   | Master Interface No. | Arbitration Type  | Programmable Slots |
|-------|----------------------|-------------------|--------------------|
| SCB0  | MI0 (DDR)            | Prog Round Robin  | 32                 |
|       | MI1 (SMC)            | Prog Round Robin  | 32                 |
|       | MI2 (DL2)            | Prog Round Robin  | 32                 |
|       | MI3 (L1C0)           | Prog Round Robin  | 32                 |
|       | MI4 (L1C1)           | Prog Round Robin  | 32                 |
|       | MI5 (SMMR)           | Prog Round Robin  | 16                 |
| SCB1  | MI0                  | Prog Round Robin  | 20                 |
| SCB2  | MI0                  | Prog Round Robin  | 10                 |
| SCB3  | MI0                  | Prog Round Robin  | 16                 |
| SCB4  | MI0                  | Prog Round Robin  | 16                 |
| SCB5  | MI0                  | Prog Round Robin  | 8                  |
| SCB6  | MI0                  | Prog Round Robin  | 4                  |
| SCB7  | MI0                  | Prog Round Robin  | 6                  |
| SCB8  | MI0                  | Prog Round Robin  | 8                  |
| SCB9  | MI0                  | Prog Round Robin  | 10                 |
| SCB10 | MI0 (CL2)            | Prog Round Robin  | 16                 |
|       | MI1 (C02Sys)         | Fixed Round Robin | 0                  |
|       | MI2 (C12Sys)         | Fixed Round Robin | 0                  |

## SCB0 Slots and Masters

**Table 2-3:** SCB0 Arbitration Default Settings for MI0 (DDR)

| Slot | Master      |
|------|-------------|
| 0    | SI0 (C0)    |
| 1    | SI2 (C1)    |
| 2    | SI4 (SCB9)  |
| 3    | SI5 (SCB5)  |
| 4    | SI6 (SCB6)  |
| 5    | SI7 (SCB8)  |
| 6    | SI8 (SCB7)  |
| 7    | SI9 (SCB1)  |
| 8    | SI10 (SCB2) |
| 9    | SI11 (SCB3) |
| 10   | SI13 (USB)  |
| 11   | SI12 (SCB4) |
| 12   | SI0 (C0)    |
| 13   | SI2 (C1)    |
| 14   | SI4 (SCB9)  |
| 15   | SI5 (SCB5)  |
| 16   | SI6 (SCB6)  |
| 17   | SI7 (SCB8)  |
| 18   | SI8 (SCB7)  |
| 19   | SI9 (SCB1)  |
| 20   | SI10 (SCB2) |

**Table 2-3:** SCB0 Arbitration Default Settings for MI0 (DDR) (Continued)

| Slot | Master      |
|------|-------------|

| 1    | SI1 (LP1)     |
| 2    | SI2 (LP2)     |
| 3    | SI3 (LP3)     |
| 4    | SI4 (UART0TX) |
| 5    | SI5 (UART0RX) |
| 6    | SI6 (UART1TX) |
| 7    | SI7 (UART1RX) |
| 8    | SI0 (LP0)     |
| 9    | SI1 (LP1)     |
| 10   | SI2 (LP2)     |
| 11   | SI3 (LP3)     |
| 12   | SI4 (UART0TX) |
| 13   | SI5 (UART0RX) |
| 14   | SI6 (UART1TX) |
| 15   | SI7 (UART1RX) |

## SCB4 Slots and Masters

**Table 2-12:** MI0 (SCB4)

| Slot | Master      |
|------|-------------|
| 0    | SI0 (DMA21) |
| 1    | SI1 (DMA22) |
| 2    | SI2 (DMA23) |
| 3    | SI3 (DMA24) |
| 4    | SI4 (DMA25) |
| 5    | SI5 (DMA26) |
| 6    | SI6 (DMA27) |
| 7    | SI7 (DMA28) |
| 8    | SI0 (DMA21) |
| 9    | SI1 (DMA22) |
| 10   | SI2 (DMA23) |
| 11   | SI3 (DMA24) |
| 12   | SI4 (DMA25) |
| 13   | SI5 (DMA26) |
| 14   | SI6 (DMA27) |
| 15   | SI7 (DMA28) |

## SCB5 Slots and Masters

**Table 2-13:** MI0 (SCB5)

| Slot | Master              |
|------|---------------------|
| 0    | SI0 (PPI0 -- DMA29) |
| 1    | SI1 (PPI0 -- DMA30) |

**Table 2-13:** MI0 (SCB5) (Continued)

| Slot | Master              |
|------|---------------------|
| 2    | SI2 (PPI2 -- DMA31) |
| 3    | SI3 (PPI2 -- DMA32) |
| 4    | SI0 (PPI0 -- DMA29) |
| 5    | SI1 (PPI0 -- DMA30) |
| 6    | SI2 (PPI2 -- DMA31) |
| 7    | SI3 (PPI2 -- DMA32) |

## SCB6 Slots and Masters

**Table 2-14:** MI0 (SCB6)

| Slot | Master              |
|------|---------------------|
| 0    | SI0 (PPI1 -- DMA33) |
| 1    | SI1 (PPI1 -- DMA34) |
| 2    | SI0 (PPI1 -- DMA33) |
| 3    | SI1 (PPI1 -- DMA34) |

## SCB7 Slots and Masters

**Table 2-15:** MI0 (SCB7)

| Slot | Master      |
|------|-------------|
| 0    | SI0 (PIXC0) |
| 1    | SI1 (PIXC1) |
| 2    | SI2 (PIXC2) |
| 3    | SI0 (PIXC0) |
| 4    | SI1 (PIXC1) |
| 5    | SI2 (PIXC2) |

## SCB8 Slots and Masters

**Table 2-16:** MI0 (SCB8)

| Slot | Master           |
|------|------------------|
| 0    | SI0 ( PVP CPDOB) |
| 1    | SI1 (PVP CPDOC)  |
| 2    | SI2 (PVP CPCO)   |
| 3    | SI3 (PVP CPCI)   |
| 4    | SI0 (PVP CPDOB)  |
| 5    | SI1 (PVP CPDOC)  |
| 6    | SI2 (PVP CPCO)   |
| 7    | SI3 (PVP CPCI)   |

## SCB9 Slots and Masters

**Table 2-17:** MI0 (SCB9)

| Slot | Master              |
|------|---------------------|
| 0    | SI0 (PVP MPDO/UDDO) |
| 1    | SI1 (PVP MPDI/UDDI) |
| 2    | SI2 (PVP MPCO/UPCO) |
| 3    | SI3 (PVP MPCI/UPCI) |
| 4    | SI4 (PVP CPDOA)     |
| 5    | SI0 (PVP MPDO/UDDO) |
| 6    | SI1 (PVP MPDI/UDDI) |
| 7    | SI2 (PVP MPCO/UPCO) |
| 8    | SI3 (PVP MPCI/UPCI) |
| 9    | SI4 (PVP CPDOA)     |

## SCB Programming Model

### SCB Register Access Restrictions

The following information applies to the SCB registers:

1. Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in unpredictable behavior of the SCB
2. Unless otherwise stated in the accompanying text:
  - Do not modify undefined register bits
  - Ignore undefined register bits on reads
  - All register bits are reset to a logic 0 by a system reset

### SCB Programming Concepts

#### Arbitration Model Configuration

The arbitration model of the SCB is programmable. Through register configuration, the arbitration model can be adjusted for the specific bandwidth and latency requirements. The arbitration model is programmable round robin with the following features:

- Each MI has its own set of arbitration slots
- Total number of arbitration slots is specific to the SCB and fixed in hardware
- Arbitration slot priority rotates each cycle
- SIs are assigned to each slot (see programming model)
- Transactions are granted to highest priority requesting master each cycle

## SCB Programming Examples

Each MI of an SCB has an Arbitration Write Channel register and an Arbitration Read Channel register which provide indexed access to the write channel and read channel arbitration parameters respectively for the MI. of the slave interfaces (SIn) connected to the SCB.

### Reading Arbitration Settings

To read arbitration parameter data (for example, get the identity of the SI assigned to an arbitration slot), use a write-followed-by-read process with bits 31-24 set to FF:

1. Write SCB\_ARBWn with the value 0xFFmm (where mm is the slot index for the following read)
2. Read the value in SCB\_ARBWn, the value is 0x00nn (where nn is identity of the SI assigned to slot mm)

### Writing Arbitration Settings

To write arbitration parameter data (for example, assign an SI to an SCB slot), use a write with bits 31-24 set to the slot number. For information about the SCBs in the processor and their slot numbers, see the SCB functional description section.

**NOTE:** No protection is imposed when you program the slots in the arbitration scheme. It is possible to remove an SI from all the slots (making the SI inaccessible).

## SCB Register Descriptions

System Cross Bar (SCB) contains the following registers.

**Table 2-18:** SCB Module Registers

| Name        | Description                                           |
|-------------|-------------------------------------------------------|
| SCB_ARBRn   | Arbitration Read Channel Master Interface n Register  |
| SCB_ARBWn   | Arbitration Write Channel Master Interface n Register |
| SCB_SLAVES  | Slave Interfaces Number Register                      |
| SCB_MASTERS | Master Interfaces Number Register                     |

### Arbitration Read Channel Master Interface n Register

Each master interface (MI) of an SCB has an SCB\_ARBRn register, providing indexed access to the read arbitration parameters of the slave interfaces (SIn) connected to that MI.

SCB\_ARBRn: Arbitration Read Channel Master Interface n Register - R/W

Reset = 0x0000 0000

## 3 Clock Generation Unit (CGU)

The Clock Generation Unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock that runs at a frequency that is multiple times the CLKIN input clock frequency. It also generates all on-chip clocks and synchronization signals. The PCU allows the application software to control the PLL module operation.

### CGU Functional Description

The CGU (clock generation unit) generates all on-chip clocks and synchronization signals based on the programmed PLL multiplication factor and dividers.

### CGU Register List

The clock generation unit (CGU) includes the phase locked loop (PLL) and the PLL control unit (PCU). The PLL generates a clock, running at a frequency that is a multiple of the CLKIN input clock's frequency. The CGU also generates all on-chip clocks and synchronization signals. The PCU permits application software control of the PLL's operation. A set of registers govern CGU operations. For more information on CGU functionality, see the CGU register descriptions.

**Table 3-1:** CGU Module Registers

| Name          | Description            |
|---------------|------------------------|
| CGU_CTL       | Control Register       |
| CGU_STAT      | Status Register        |
| CGU_DIV       | Divisor Register       |
| CGU_CLKOUTSEL | CLKOUT Select Register |

## ADSP-BF60x CGU Interrupt List

**Table 3-2:** ADSP-BF60x CGU Interrupt List

| Description | ID  | DMA Channel | Sensitivity |
|-------------|-----|-------------|-------------|
| CGU0 Event  | 1   |             | PULSE/EDGE  |
| CGU0 Error  | 129 |             | LEVEL       |

## ADSP-BF60x CGU Trigger List

**Table 3-3:** Masters ADSP-BF60x CGU Trigger List

| Description | ID | Sensitivity |

## CGU Definitions

### CGU

Clock Generation Unit which is comprised of the PLL and PCU. The CGU generates the following clocks:

**Table 3-5:** Clock Descriptions

| Clock  | Description                                                                                 |
|--------|---------------------------------------------------------------------------------------------|
| PLLCLK | Provides the source from which all clocks below are derived from unless the PLL is bypassed |
| CCLK0  | Core Clock 0                                                                                |
| CCLK1  | Core Clock 1                                                                                |
| SYSCLK | Clock for system buses and provides the source from which SCLK0 and SCLK1 are derived       |
| SCLK0  | PVP and all other peripherals not clocked by SCLK1                                          |
| SCLK1  | SPORT, SPI, and ACM peripherals clock                                                       |
| DCLK   | Dynamic memory clock                                                                        |
| OUTCLK | OUTCLK is a possible source for SYS_CLKOUT                                                  |

### DPM

Dynamic Power Management Controller

### PCU

PLL control unit

### PLL

Phase locked loop

### RCU

Reset control unit

## CGU PLL Block Diagram

The following figure is a top level block diagram of the phase locked loop (PLL). The main blocks of the PLL are the phase frequency detector (PFD), the charge pump, the loop filter, and the voltage controlled

oscillator (VCO) which multiplies SYS\_CLKIN to a higher frequency. The output of these blocks is called PLLCLK. The PLLCLK is divided to form CCLK0, CCLK1, SYSCCLK, DCLK, and OUTCLK. The SYSCCLK is further divided to form SCLK0 and SCLK1. The OUTCLK is routed to the CLKOUT module shown below so it can be selected as one of the SYS\_CLKOUT sources.

**Figure 3-1: PLL Top Level Block Diagram**

The following figure is a conceptual representation of the CLKOUT module. As shown in the PLL Top Level Block Diagram, many clocks are available on the output pin **SYS\_CLKOUT**. The selection of which clock outputs on **SYS\_CLKOUT** is controlled by **CGU\_CLKOUTSEL.CLKOUTSEL**.

**Figure 3-2:** CLKOUT Module

## CGU Event Control

The CGU is capable of generating a CGU Event or CGU Error for several different causes.

### CGU Event

The CGU Event interrupt is used for different purposes. After a frequency change, a CGU Event indicates that the PLL has locked and clocks are synchronized. The CGU Event interrupt can be used to break the core idle if the core was idled while change frequencies. While in ACTIVE mode, a CGU Event indicates that the PLL has locked. Before boot the CGU Event is used to signal the RCU to kick off the boot process.

### CGU Error

If the PLL fails to lock, the PLL will be disabled and a CGU Error is triggered. In addition, `CGU_STAT.PLOCKERR` is set. The PLL resets itself when it is disabled. If the lock error happens during reset, system reset will be exited and a CGU Event will be triggered. If the failed lock occurs during a frequency change the cores exit idle. In order to clear the CGU Event in an Interrupt Service Routine, write to

`CGU_CTL.MSEL` or `CGU_CTL.DF`. This makes the PLL exit the error state (`CGU_STAT.PLOCKERR` is cleared and the `CGU_EVENT` is de-asserted) and re-lock. This occurs even if the new `CGU_CTL.MSEL` and `CGU_CTL.DF` values are the same as the old values. `CGU_CTL.LOCK` and `CGU_CTL.WFI` settings will still apply. If the PLL lock error occurred during a hardware or software triggered system reset, once out of reset the system is functional and can boot. If the PLL lock error occurs during a PLL frequency change, the CGU Event interrupt makes the cores exit idle, as in the non error case.

The `CGU_STAT.WDIVERR` indicates a write access to the `CGU_DIV` register (to trigger an alignment sequence or to change `CGU_DIV.CSEL`, `CGU_DIV.SYSSEL`, `CGU_DIV.S0SEL`, `CGU_DIV.S1SEL`, or `CGU_DIV.DSEL`) while the PLL is locked, but still aligning the clocks. This generates a CGU Error. If this error occurs it should be cleared and the desired values should be written to `CGU_DIV` again.

The `CGU_STAT.WDFMSERR` indicates a write access to the `CGU_CTL` register to change `CGU_CTL.DF` or `CGU_CTL.MSEL` while the PLL is locking. This generates a CGU Error. If this error occurs wait until the PLL has finished locking, clear the error, and write the desired `CGU_CTL.DF` or `CGU_CTL.MSEL` change again.

The `CGU_STAT.DIVERR` indicates a clock divisor value error, occurring when a CCLK divisor is greater than the SYSCLK divisor, as in: `CGU_DIV.CSEL > CGU_DIV.SYSSEL`. The CGU issues a CGU Error for this condition. If this error occurs it should be cleared and the new values should be written to `CGU_DIV` such that `CGU_DIV.CSEL` is less than or equal to `CGU_DIV.SYSSEL`.

## **CGU Generated Bus Errors**

The CGU will generate a bus error if a read or write transaction is attempted to an unused address within the CGU address range or if a misaligned access is made to an existing CGU register. In addition to the bus error `CGU_STAT.ADDRERR` will be set. If a write to a write protected DPM register is attempted a bus error will also be generated. In addition, `CGU_STAT.LWERR` will be set.

## **CGU Programming Model**

This section describes the programming concepts and mode configuration techniques for the CGU.

## **CGU Mode Configuration**

This section provides procedures related to clock and PLL configuration.

## Changing the PLLCLK Frequency

To change the PLLCLK frequency, write new values to `CGU_CTL.MSEL` or `CGU_CTL.DF`. Any time the PLL relocks, all core and system clocks are aligned.

1. Read `CGU_STAT` register. Verify that:
  - a. `PLLEN` bit = 1 (PLL enabled)
  - b. `PLLLK` bit = 1 (PLL is not locking) or `PLLLKERR` bit = 1 (PLL lock error, the PLL failed to lock)
  - c. `CLKSALGN` = 0 (clocks aligned)
2. Write the desired `CSEL`, `SOSEL`, `SYSSEL`, `S1SEL`, `DSEL` and `OSEL` values to the `CGU_DIV` register with the `UPDT` bit = 0.
3. Write the desired `DF` and `MSEL` values to the `CGU_CTL` register.
  - a. To change the PLL frequency while the cores are idle, write to the `CGU_CTL` register with the `WIDLE` bit set.
  - b. To change the PLL frequency while the cores are active, write to the `CGU_CTL` register with the `WIDLE` bit cleared.

*AFTER COMPLETING THIS TASK:*

This sequence updates the corresponding CGU registers, bypasses the PLL, makes the PLL lock to the new `MSEL` or `DF` values, changes the `CCLKn`, `SYSCLK`, `SCLKn`, `DCLK`, and `OCLK` frequencies and exits PLL bypass with all clocks aligned. When exiting the PLL bypass state, a CGU Event occurs.

The `CGU0_STAT` register exits this sequence with the `PLLEN` and `PLLLK` bits set, and the `PLLBP` and `CLKSALGN` bits cleared. The `PLLLK`, `PLLBP` and `CLKSALGN` bits can be polled to discover when the PLL is locked and the clocks are aligned.

Changing the PLL's frequency is allowed while the processor is in active (PLL bypassed) mode but the effect of the change is visible only after the transition to full-on mode. While in active mode a CGU Event occurs, indicating that the PLL has locked.

Changing the PLL frequency causes the `DCLK` frequency to change, therefore accessing the DDR memory, or the DDR memory controller's registers while the PLL and clocks frequencies' change is in progress may have unpredictable results.

## Changing the CCLKn, SYSCLK, or SCLKn frequency Without Modifying the PLLCLK Frequency

To change the clock frequencies is done by writing new `CGU_DIV.CnSEL`, `CGU_DIV.SYSSEL`, or `CGU_DIV.SnSEL` values. The frequency change occurs only when the PLL is not bypassed. Any time the

CCLKn, SYSCLK, or SCLKn clock frequencies is changed, they all exit the frequency change sequence aligned. The CGU\_SYSDCLK\_ALGN is not asserted even if the SYSCLK and the DCLK frequencies are equal.

1. Read the CGU\_STAT register. Verify that CLKSALGN = 0 (clocks aligned)
2. Write the desired CSEL, SOSEL, SYSSEL, S1SEL, DSEL and OSEL values to the CGU0\_DIV registers with the UPDT bit = 1.

*ADDITIONAL INFORMATION:* This write updates the CGU\_DIV register and changes the CCLKn, SYSCLK or SCLKn frequencies and aligns these clocks. When the clocks are aligned a CGU Event occurs.

*AFTER COMPLETING THIS TASK:*

The CGU\_STAT register exits this sequence with the CLKSALGN bit cleared. The CLKSALGN bit can be polled to discover when the clocks are aligned. Any write to the CGU\_DIV register intended to change an xSEL field while the CLKSALGN bit = 1 (clocks alignment in progress) triggers a bus error and the CGU\_DIV register is not modified.

Programming the SYSCLK frequency to a higher value than CCLKn also triggers an MMR access bus error and the CGU\_DIV register is not modified.

Writing to the CGU\_DIV register is allowed while the processor is in active (PLL bypassed) mode but the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory while changing the SYSCLK frequency is not supported and may have unpredictable results.

## Changing the DCLK Clock Frequency

To change the DCLK clock frequency write a new CGU\_DIV.DSEL value. The frequency change occurs only when the PLL is not bypassed. Any time DCLK clock frequency is changed, DCLK, CCLKn, SYSCLK and SCLKn clocks exit the frequency change sequence aligned. The CGU\_SYSDCLK\_ALGN bit = 1 if the SYSCLK and the DCLK frequencies are equal.

1. Read the CGU0\_STAT register. Verify that CLKSALGN = 0 (clocks aligned)
2. Write the desired DSEL value to the CGU0\_DIV register, with the UPDT bit = 1.

*ADDITIONAL INFORMATION:* This write updates the CGU\_DIV register, changes the DCLK frequency, and aligns all clocks except OUTCLK.

*AFTER COMPLETING THIS TASK:*

The CGU\_STAT register exits this sequence with the CLKSALGN bit = 0. The CLKSALGN bit can be polled to discover when the clocks are aligned. Any write to the CGU\_DIV register intended to change the DSEL field while CLKSALGN is = 1 (clocks alignment in progress) triggers an MMR access bus error and the CGU\_DIV register is not modified. When clocks are aligned a CGU event occurs.

Writing to `CGU0_DIV.DSEL` is allowed while the processor is in active (PLL bypassed) mode but the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

Accessing the DDR memory, or the DDR memory controller's registers while changing the `DCLK` frequency is not supported and may have unpredictable results.

## Changing the OUTCLK Frequency

To change the OUTCLK clock frequency, write a new `CGU_DIV.OSEL` value. Any time OUTCLK clock frequency is changed, the OUTCLK, CCLKn, SYCLK and SCLKn clocks exit the frequency change sequence aligned. The `CGU_SYSDCLK_ALGN` signal is not modified.

1. Read `CGU_STAT` register. Verify that `CLKSALGN = 0` (clocks aligned)
2. Write desired `OSEL` value with the `UPDT` bit 1 to the `CGU0_DIV` register.

*ADDITIONAL INFORMATION:* This write updates the `CGU_DIV` register, changes the `DCLK` frequency, and aligns all clocks except OUTCLK.

*AFTER COMPLETING THIS TASK:*

The `CGU_STAT` register exits this sequence with the `CLKSALGN` bit = 0. The `CLKSALGN` bit can be polled to discover when the clocks are aligned. Any write to the `CGU_DIV` register intended to change the `DSEL` field while `CLKSALGN = 1` (clock alignment in progress) triggers an MMR access bus error and the `CGU_DIV` register is not modified. When clocks are aligned a CGU event occurs.

Writing to the `OSEL` field in the `CGU_DIV` register is allowed while the processor is in active (PLL bypassed) mode but the effect of the write is visible only after the transition to full-on (PLL not bypassed) mode.

## Aligning All Clocks

To align CCLKn, SYCLK, SCLKn, DCLK and OUTCLK clocks write 1 to `CGU0_DIV.ALGN`. The `CSEL`, `SYSEL`, `SnSEL`, `DSEL` or `OSEL` may be changed if a frequency change is also required. The `CGU_SYSDCLK_ALGN` is asserted if SYCLK and DCLK frequencies are equal.

1. Read the `CGU_STAT` register. Verify that `CLKSALGN = 0` (clocks aligned).
2. Write 1 to the `ALGN` bit in `CGU_DIV` register. All other fields may or may not change.

*ADDITIONAL INFORMATION:* This write does not alter the `CGU_DIV` register unless any of the `xSEL` fields is modified. When clocks are aligned a CGU event occurs.

*AFTER COMPLETING THIS TASK:*

The `CGU_STAT` register exits this sequence with the `CLKSALGN` bit = 0. The `CLKSALGN` bit can be polled to discover when the clocks are aligned. Any write to the `CGU0_DIV` register intended to align clocks or to

change an `xSEL` field while `CLKSALGN = 1` (clocks alignment in progress) triggers an MMR access bus error and the `CGU0_DIV` register is not modified.

Writing 1 to `CGU0_DIV.ALGN` has no effect while the processor is in active (PLL bypassed) mode. Accessing the DDR memory while changing the `DCLK` or `SYSCLK` frequencies is not supported and may have unpredictable results.

## Valid ADSP-BF60x `CGU_CTL.MSEL` Bit Settings

The valid range of `CGU_CTL.MSEL` settings is from 8 to 50 in decimal. All other settings are reserved. In addition to this requirement, `CGU_CTL.MSEL` must be set such that the minimum and maximum `PLLCLK` specified in the data sheet is not violated.

## CGU Register Descriptions

Clock Generation Unit (CGU) contains the following registers.

**Table 3-6:** CGU Module Registers

| Name                       | Description            |
|----------------------------|------------------------|
| <code>CGU_CTL</code>       | Control Register       |
| <code>CGU_STAT</code>      | Status Register        |
| <code>CGU_DIV</code>       | Divisor Register       |
| <code>CGU_CLKOUTSEL</code> | CLKOUT Select Register |

## Control Register

The `CGU_CTL` controls the clock generation divisors for `SYS_CLKIN` and the PLL. Read after write accesses to the `CGU_CTL` register returns the new value even if the clock's frequency change is still in progress.

**CGU\_CTL: Control Register - R/W**

Reset = 0x0000 1000

**Figure 3-3:** CGU\_CTL Register Diagram

**Table 3-7:** CGU\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|         |          | 1      Lock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 30      | WFI      | Wait For Idle.<br>Modifying the PLL multiplier requires the PLL to re-lock and once the PLL locks, clocks have to be synchronized. Changes to the CGU_CTL.MSEL and the CGU_CTL.DF result in bypassing the PLL. The CGU_CTL.WFI force the PLL to wait for all processor cores to be in an idle or reset state before changing frequencies as a result of change to the CGU_CTL.MSEL or CGU_CTL.DF fields. Write accesses to CGU_CTL to change CGU_CTL.DF or CGU_CTL.MSEL while the PLL is locking sets the CGU_STAT.WDFMSERR bit. |

## Status Register

The `CGU_STAT` register reflects the PLL status and errors detected during the PLL configuration. This register may be cleared asynchronously by a reset signal from the RCU module. All bits---except those defined as W1C (write-1-to-clear)---are read only.

**CGU\_STAT: Status Register - R/W**

Reset = 0x0000 03f5

**Figure 3-4:** CGU\_STAT Register Diagram

**Table 3-8:** CGU\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                         |
|---------|----------|---------------------------------------------------------------------------------|
| 21      | PLOCKERR | PLL Lock Error.<br>The CGU_STAT.PLOCKERR indicates that the PLL failed to lock. |
|         |          | 0 No Error                                                                      |
|         |          | 1 PLL Lock Error                                                                |

**Table 3-8:** CGU\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20      | WDIVERR  | Write to DIV Error.<br>The CGU_STAT.WDIVERR indicates a write access to the CGU_DIV register (to trigger an alignment sequence or to change CGU_DIV.CSEL, CGU_DIV.SYSSEL, CGU_DIV.S0SEL, CGU_DIV.S1SEL, or CGU_DIV.DSEL) while the PLL is locked, but still aligning the clocks. Read after write accesses to the CGU_STAT and CGU_DIV registers return the new value even if the clock frequency change is still in progress. |
|         |          | 0 No Error                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Divisor Register

The `CGU_DIV` register controls clock divisors for core clocks, system clocks, external (off core) memory clocks, and output clock. Read after write accesses to the `CGU_DIV` register returns the new value even if the clock's frequency change is still in progress.

### CGU\_DIV: Divisor Register - R/W

Reset = 0x0408 4844

## 4 System Protection Unit (SPU)

The system protection unit (SPU) provides features that let you protect system resources from errant writes. A number of protection categories (types of registers to protect) are available.

### SPU Features

The System Protection Unit includes the following abilities.

- To write-protect system MMR from certain system masters.
- To simultaneously lock multiple peripheral configuration registers.
- To write-protect and block access to its own write-protection registers from other system masters.

### SPU Functional Description

The SPU has a register associated with each peripheral. Each of these write-protection registers has the exact same bits that correspond to a particular SMMR master (Core 0, Core 1, MDMA, for example). When the bits are set, the corresponding SMMR masters are locked out of accessing the associated peripheral's register address space. The bits in the register can be cleared to allow access to the peripheral's registers again. Any writes that are in progress when write-protection is initiated will complete before subsequent writes are blocked.

In the following figure, each write-protect register in the SPU is associated with a particular peripheral.

**Figure 4-1:** SPU Write Protect Registers

The SPU also has global locking capability. When enabled, a system-wide global lock signal is active. Some peripherals have a lock enable bit in their control register. When this bit is set, the peripheral recognizes the global lock signal and blocks further write-accesses to its own control register. Access to the peripheral's configuration register is re-enabled when global lock is turned off in the SPU.

The following figure is a conceptual diagram where a peripheral will block any write attempts to its control register if the global lock signal from the SPU is active AND the global lock enable bit is set in the peripheral's control register.

### Figure 4-2: Global Locking

The SPU can write protect its own registers. When the write protection register lock bit is set and global locking is enabled, accesses to the SPU write-protection registers are blocked. To re-enable write access to the write-protection registers in the SPU, global locking must be disabled.

In the following figure a write-protect register in the SPU blocks write-attempts to the associated peripheral's MMR space. The bits in the write-protect register specify which masters to block write-access from.

**Figure 4-3:** SPU Write-Protect Register Blocking Access from System Master 0 and Core Master 1

## SPU Register List

The system protection unit (SPU) provides a set of registers that allow you to protect system resources from errant writes. The protection categories are global lock (protects configuration registers) and write protect register lock (protects the write protect register). For more information on SPU functionality, see the SPU register descriptions.

**Table 4-1:** SPU Module Registers

| Name     | Description              |
|----------|--------------------------|
| SPU_CTL  | Control Register         |
| SPU_STAT | Status Register          |
| SPU_WPn  | Write Protect Register n |

## SPU Definitions

### Write-Protect Register

Memory mapped registers in the SPU. Each register correlates to a specific peripheral instance. It controls the write access to the peripheral's register set.

### Global Locking

SPU's ability to prevent write access to multiple peripheral's control register at once.

## SPU Block Diagram

The figure below shows a system level block diagram of where the SPU is in the system. It sits in between the SMMR interface and the system crossbar. Depending on the configuration of the SPU write-protect registers, it can block access to certain peripherals from certain SMMR masters.

SPU System Level Block Diagram

## SPU Architectural Concepts

As shown in the block diagram, the SPU sits between the System Crossbar (SCB) and the SMMR interface to the peripherals. Any MMR access to any peripheral from any master comes through the SCB and is gated by the SPU. Depending on the configuration of the write-protection registers in the SPU, the SPU may or may not allow the MMR write to go through.

## SPU Event Control

The system protection unit provides write protection against a peripheral's MMRs and its own write-protect registers. If a write attempt is made to any peripheral's MMR and was locked, the SPU will block the write and generate a bus error to the master that attempted the write. That master may or may not generate an event based upon the returned error. The SPU does not generate an event for blocked write attempts.

The SPU can also lock its own registers from write attempts. If a write-attempt was made to a locked register in the SPU, the SPU blocks it and records it as an error in `SPU_STAT.LWERR`. Again, the SPU generates a bus error to the master that attempted the write. The master may or may not generate an event based upon the returned error. The SPU does not generate an event for a blocked write access to an SPU register.

## SPU Programming Model

The system protection unit (SPU) consists of write-protect registers. Each one corresponds to a different peripheral instance. Bits in the write-protect registers correspond to system masters that can modify the

MMR contents of the peripherals. By writing to these write-protect registers, the corresponding peripheral's memory mapped registers will be write protected against masters whose bits in the write-protect register have been set.

Another capability of the SPU is to globally lock peripherals' control register. Peripherals that support this feature will have a lock enable bit in their control register. When the global lock signal is active from the SPU and the peripheral's lock enable bit is set, the peripheral blocks any more write attempts to its control register from any master. If the lock enable bit of a peripheral is not set and the global lock signal is active, access to that peripheral's control register is still allowed. To grant access again, the global lock signal from the SPU must be disabled. This is done by writing the value 0xAD into the GLCK field of the SPU\_CTL register.

Another protection mechanism that the SPU offers is write protection against the write-protection registers. If the Write Protect Register Lock (WPLCK) bit is set in the SPU\_CTL register and the global lock signal is active, writes to the SPU's write-protect registers will be blocked. To re-enable access to the write-protect registers in the SPU, the global lock signal must be deactivated by writing 0xAD into the GLCK field of the SPU\_CTL register.

## **SPU Mode Configuration**

The SPU can provide address range wide protection by write-protecting the peripherals MMR address range from system MMR masters. It can also provide register wide protection by using Global Locking. Peripherals that support this feature can enable it their respective configuration register. When the SPU enables the Global Lock signal, all subsequent writes to the peripheral's configuration register are blocked until the Global Lock signal is deasserted. Similarly, the SPU's own write-protection registers can be write protected using the Global Lock signal as well. All these modes of operation can be used in conjunction.

## **Locking Write-Protect Registers**

Use the following steps to lock (write protect) a register.

1. Set SPU\_CTL.WPLCK bit and set the SPU\_CTL.GLOCK field to something other than 0xAD.

*RESULT:*

The SPU write-protect registers are blocked from further write accesses.

## Protecting a Peripheral

Use the following procedure to protect a peripheral

1. Determine which peripheral needs protection and locate the corresponding write-protect register in the SPU.
2. Determine which SMMR master(s) the peripheral needs to be protected from and set the corresponding bit(s) in the write-protect register for the peripheral in the SPU.

### *RESULT:*

After setting the write-protect register for the particular peripheral, the SMMR master(s) will be blocked from writing to any MMR in the peripheral's address space until the bits in the write-protect register are cleared.

## SPU Register Descriptions

System Protection Unit (SPU) contains the following registers.

**Table 4-2:** SPU Module Registers

| Name     | Description              |
|----------|--------------------------|
| SPU_CTL  | Control Register         |
| SPU_STAT | Status Register          |
| SPU_WPn  | Write Protect Register n |

## Control Register

The SPU control register (SPU\_CTL) provides a global lock for configuration registers and write protection for registers.

SPU\_CTL: Control Register - R/W

Reset = 0x0000 00ad

Figure 4-4: SPU\_CTL Register Diagram

Table 4-3: SPU\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | WPLCK    | Write Protect Register Lock.<br>The SPU_CTL.WPLCK works with the SPU_CTL.GLCK field. If the write protect register lock is enabled (SPU_CTL.WPLCK bit =1) and the global lock is enabled, writes to the SPU_WPn register are disabled (locked out). |
|         |          | 0      Disable                                                                                                                                                                                                                                      |
|         |          | 1      Enable                                                                                                                                                                                                                                       |
| 7:0     | GLCK     | Global Lock Disable.<br>The SPU_CTL.GLCK controls the global lock of configuration registers. Writing 0xAD to this field disables the lock, and writing any other value enables the lock.                                                           |

Status Register

The SPU\_STAT register indicates the error and lock status for the SPU.

**SPU\_STAT: Status Register - R/W**

Reset = 0x0000 0000

**Figure 4-5:** SPU\_STAT Register Diagram

**Table 4-4:** SPU\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LWERR    | Lock Write Error.<br>The SPU_STAT.LWERR is write-1-to-clear and indicates whether there has been an attempted write to a register with its LOCK bit set while SPU_CTL.GLCK was asserted. |
|         |          | 0 Inactive                                                                                                                                                                               |
|         |          | 1 Active                                                                                                                                                                                 |
| 30      | ADDRERR  | Address Error.<br>The SPU_STAT.ADDRERR is write-1-to-clear and indicates whether there has been an attempted write to a read-only register or an access an invalid address.              |
|         |          | 0 Inactive                                                                                                                                                                               |
|         |          | 1 Active                                                                                                                                                                                 |
| 0       | GLCK     | Global Lock Status.<br>The SPU_STAT.GLCK indicates whether the global lock is enabled or disabled.                                                                                       |
|         |          | 0 Disabled (global_lock=0)                                                                                                                                                               |
|         |          | 1 Enabled (global_lock=1)                                                                                                                                                                |

Write Protect Register n

In the system, each SPU\_WPn register is assigned to a specific MMR address range associated with one peripheral. When the appropriate bits are set, writes to the peripheral from a specific master are blocked and an error is returned to the master. For more information, see the SPU functional description.

# 5 Dynamic Power Management (DPM)

The dynamic power management (DPM) unit of the processor controls transitions between different power saving modes. The DPM also allows individual clock domains to be enabled and disabled.

## DPM Features

The DPM allows programs to control the processor's power mode as follows.

- The capability to shut off individual clock domains to save power
- The capability to bypass the PLL for power savings
- HIBERNATE mode allows `VDD_INT` to be shut off in order to save power
- Multiple external wake-up sources

## DPM Functional Description

The processor supports four different power domains, which maximizes flexibility while maintaining compliance with industry standards and conventions. By isolating the internal logic of the processor into its own power domain, separate from other I/O, the processor can take advantage of dynamic power management without affecting the other I/O devices. There are no sequencing requirements for the various power domains, but all domains must be powered according to the appropriate specifications, even if the feature/peripheral is not used. For more information on power domains, see the *ADSP-BF60x Blackfin Dual Core Embedded Processor* data sheet.

The dynamic power management feature of the processor allows the processor's core clock frequency ( $f_{\text{CLK}}$ ) to be dynamically controlled.

## DPM Register List

The dynamic power management (DPM) unit includes the phase locked loop (PLL) enable/disable features, deep sleep and hibernate mode controls, and clock domain enable/disable features. The combination of these features and controls provide selective and flexible power management. A set of registers govern DPM operations. For more information on DPM functionality, see the DPM register descriptions.

**Table 5-1:** DPM Module Registers

| Name               | Description                              |
|--------------------|------------------------------------------|
| DPM_CTL            | Control Register                         |
| DPM_STAT           | Status Register                          |
| DPM_CCBF_DIS       | Core Clock Buffer Disable Register       |
| DPM_CCBF_EN        | Core Clock Buffer Enable Register        |
| DPM_CCBF_STAT      | Core Clock Buffer Status Register        |
| DPM_CCBF_STAT_STKY | Core Clock Buffer Status Sticky Register |
| DPM_SCBF_DIS       | System Clock Buffer Disable Register     |
| DPM_WAKE_EN        | Wakeup Enable Register                   |
| DPM_WAKE_POL       | Wakeup Polarity Register                 |
| DPM_WAKE_STAT      | Wakeup Status Register                   |
| DPM_HIB_DIS        | Hibernate Disable Register               |
| DPM_PGCNTR         | Power Good Counter Register              |
| DPM_RESTOREn       | Restore n Register                       |

## ADSP-BF60x DPM Interrupt List

**Table 5-2:** ADSP-BF60x DPM Interrupt List

| Description | ID  | DMA Channel | Sensitivity |
|-------------|-----|-------------|-------------|
| DPM0 Event  | 131 |             | LEVEL       |

## DPM Definitions

To make the best use of the DPM, it is useful to understand the following terms.

### **Active**

Power saving mode in which the PLL is bypassed but still enabled.

### **Active with PLL disabled**

Power saving mode in which the PLL is bypassed and disabled.

### **CGU**

Clock Generation Unit which is comprised of the PLL and PCU

### **Deep Sleep**

Power saving mode in which all CCLKs are gated.

### **DPM**

Dynamic Power Management Controller

### **Full On**

The normal operating mode in which all clock domains are derived from the PLL.

### **Hibernate**

A power saving mode in which VDD\_INT can be shut off and the contents of on-chip memory isn't retained.

### **PCU**

PLL control unit

### **PLL**

Phase locked loop

### **RCU**

Reset control unit

## DPM Operating Modes

The DPM includes several operating modes described below. They are RESET, FULL-ON, ACTIVE, ACTIVE with PLL Disabled, DEEP SLEEP, and HIBERNATE.

## RESET

RESET is the initial state of the processor and is the result of a hardware or software triggered event. Entering RESET is not triggered by the DPM itself, but by the external `SYS_HWRST` pin or by the RCU. The DPM responds, as other functional units do, by transitioning to its default state with the exception of certain registers (described under HIBERNATE below) that are preserved if returning from hibernate. From RESET the DPM always transitions to FULL-ON.

## FULL-ON

FULL-ON is the DPM's default state after RESET. In this mode the processor can reach its maximum clock rate and power dissipation can be at its highest. The DPM transitions to ACTIVE if `DPM_CTL.PLLBPST` is set, to DEEP SLEEP if `DPM_CTL.DEEPSLEEP` is set, and to HIBERNATE if `DPM_CTL.HIBERNATE` is set.

## ACTIVE

In ACTIVE power is reduced on the `VDD_INT` domain (compared to FULL-ON) by bypassing the PLL and running clock domains at the `SYS_CLKIN` frequency. The processor is fully functional. The DPM transitions to FULL ON if `DPM_CTL.PLLBPCL` is set, ACTIVE with PLL disabled if `DPM_CTL.PLLDIS` is set, to DEEP SLEEP if `DPM_CTL.DEEPSLEEP` is set, and to HIBERNATE if `DPM_CTL.HIBERNATE` is set.

## ACTIVE with PLL Disabled

In ACTIVE with PLL Disabled power is reduced on the `VDD_INT` domain (compared to ACTIVE) by disabling the PLL in addition to running all units at the `SYS_CLKIN` frequency. The processor is fully functional. The DPM transitions to ACTIVE if `DPM_CTL.PLLDIS` is cleared, to DEEP SLEEP if `DPM_CTL.DEEPSLEEP` is set, and to HIBERNATE if `DPM_CTL.HIBERNATE` is set.

## DEEP SLEEP

DEEP SLEEP is entered by setting `DPM_CTL.DEEPSLEEP` and having all cores in idle. It is the programs responsibility in software to guarantee that system transfers including DMA are stopped before going to idle in each core and entering DEEP SLEEP. In this state power on the `VDD_INT` domain is reduced (compared to ACTIVE or GATED ACTIVE) by gating all the core and system clocks, and disabling the PLL.

Enabled hardware wake-ups or a hardware reset can make the part exit DEEP SLEEP. The `WSn` bits in `DPM_WAKE_EN` and `DPM_WAKE_POL` registers determine which hardware wake ups are enabled and what their polarity is. Wake-up assertions are latched only if they are enabled. The enabled wake-up assertion that occurs first is recorded in `DPM_WAKE_STAT`. To see which wake-up sources your processor reports see the BF60x Wake-Up Sources topic.

When a wake-up occurs, the DPM signals a DPM event interrupt to the SEC, transitions to ACTIVE mode and enables all clocks domains that are not disabled in the `DPM_SCBF_DIS` register. The DPM event interrupt will stay active until the user clears any bits that are set in `DPM_WAKE_STAT`. The DPM event interrupt is the first indication that the processor has exited DEEP SLEEP. It can be enabled in the SEC to make a core exit idle and to enable the corresponding core clock buffer. An alternate option to wake up a core is to enable the CGU event interrupt which will assert after the PLL locks.

## HIBERNATE

In HIBERNATE there is no power dissipation on the `VDD_INT` domain as long as the voltage regulator powering `VDD_INT` is shut off. If state information, data, or code needs to be preserved it can be stored in the `DPM_RESTORE` registers or in external memory. If dynamic memory is used the memory device needs to be placed into self-refresh mode before going to hibernate.

HIBERNATE is entered by setting `DPM_CTL.HIBERNATE`. It is the programs responsibility in software to guarantee that system transfers including DMA are stopped before entering HIBERNATE.

Once `DPM_CTL.HIBERNATE` has been set, the DPM will preserve the state of `DPM_WAKE_EN`, `DPM_WAKE_POL`, `DPM_HIB_DIS`, `DPM_PGCNTR`, and all `DPM_RESTORE` registers in the DPM-HV which is powered by the `VDD_EXT` domain. All other registers (with the exception of those mentioned in the RCU chapter) and on-chip memory will be erased once `VDD_INT` is powered down. After the contents of the registers listed above are moved to storage on the `VDD_EXT` domain, the `SYS_EXTWAKE` signal is de-asserted to indicate that it is safe to shut off the regulator providing voltage to `VDD_INT`.

Enabled hardware wake-ups or a hardware reset can begin the process of exiting HIBERNATE. The `WSn` bits in `DPM_WAKE_EN` and `DPM_WAKE_POL` registers determine which hardware wake ups are enabled and what their polarity is. Wake-up assertions are latched only if they are enabled. The enabled wake-up assertion that occurs first is recorded in `DPM_WAKE_STAT`. After a wake-up occurrence is latched by the processor, the `SYS_EXTWAKE` signal will be asserted to indicate that the regulator supplying `VDD_INT` should begin to ramp up. The DPM will then wait for both the `SYS_PWRGD` signal to be asserted and for the `DPM_PGCNTR.CNT` counter to expire which indicate that `VDD_INT` has been restored within the operating conditions specified in the data sheet. For more information about the Power Good Counter and `SYS_PWRGD` signal see [Ensuring VDD\\_INT is Restored Before Booting](#).

Once `VDD_INT` is restored, `SYS_PWRGD` is asserted, and `DPM_PGCNTR.CNT` is expired, the processor exits HIBERNATE and goes to RESET and the PLL begins locking. While the PLL is locking `DPM_WAKE_EN`, `DPM_WAKE_POL`, `DPM_HIB_DIS`, `DPM_PGCNTR`, and all `DPM_RESTORE` registers are restored from the DPM-HV. After coming out of RESET and locking the PLL the processor begins executing the boot code. Some processors support memory boot when returning from hibernate (instead of the boot mode selected by the `SYS_BMODE` signals). For more information see the booting chapter.

**Figure 5-1: Operating Modes and Transitions**

## Ensuring VDD\_INT is Restored Before Booting

Before the processor boots after returning from HIBERNATE VDD\_INT must be restored. This topic discusses how to signal to the processor that VDD\_INT has been restored.

After a wake-up occurrence is latched by the DPM while in HIBERNATE, the DPM power good counter will begin decrementing and the SYS\_EXTWAKE signal will be asserted to indicate to the regulator supplying VDD\_INT that it should begin to ramp up. It is the user's responsibility to then signal the DPM through software (the DPM power good counter in the DPM\_PGCNTR register) or hardware (the SYS\_PWRGD signal) that it is safe to begin the boot process. Note that the DPM will not kick off the boot process until SYS\_PWRGD is asserted and the DPM\_PGCNTR.CNT counter is expired.

## Using the Power Good Counter to Ensure That Internal Power is Restored

In order to use the software approach, which utilizes the DPM power good counter in the DPM\_PGCNTR register, it is suggested that SYS\_PWRGD be pulled up to VDD\_EXT. The DPM will then have to wait only for the DPM power good counter to expire before kicking off the boot process. It is the user's responsibility to select the appropriate setting for DPM\_PGCNTR.CNT such that when the counter expires, VDD\_INT has been restored to within the operating conditions specified in the data sheet. The amount of time that the counter takes to expire is dependent on both the DPM\_PGCNTR.CNT setting and the SYS\_CLKIN frequency according to this equation:

$$\text{Expiration Time [ms]} = \text{Cycle Count} * 16 * \text{SYS\_CLKIN Period [ms]}$$

The text in brackets indicates that both the expiration time and SYS\_CLKIN period are expressed in milliseconds. To determine the cycle count refer to the following table which shows cycle counts for the different DPM\_PGCNTR.CNT settings.

**Table 5-3:** Cycle Counts for DPM\_PGCNTR.CNT Settings

| DPM_PGCNTR.CNT Setting            | Cycle Count   |
|-----------------------------------|---------------|
| 0x0004                            | 128 (Default) |
| 0x0080                            | 4,096         |
| 0x0100                            | 8,192         |
| 0x0200                            | 16,384        |
| 0x0400                            | 32,768        |
| 0x0800                            | 65,536        |
| 0x1000                            | 131,072       |
| 0x2000                            | 262,144       |
| 0x4000                            | 524,288       |
| 0x8000                            | 1,048,576     |
| All other values not listed above | Reserved      |

The following table shows examples of different SYS\_CLKIN frequencies and DPM\_PGCNTR.CNT settings and the resulting power good counter expiration times. Note that these are example calculations only and that the SYS\_CLKIN frequency selected must be within the range allowed by the data sheet for your processor.

**Table 5-4:** Example DPM Counter Expiration Time Calculations

| DPM_PGCNTR.CNT<br>Setting | Cycle Count (Cycles) | SYS_CLKIN<br>Frequency (MHz) | SYS_CLKIN Period<br>(ms) | Expiration Time (ms) |
|---------------------------|----------------------|------------------------------|--------------------------|----------------------|
| 0x0400                    | 32,768               | 50                           | 0.00002                  | 10.45696             |
| 0x0800                    | 65,536               | 40                           | 0.000025                 | 26.2144              |
| 0x4000                    | 524,288              | 25                           | 0.00004                  | 335.54432            |

## Using SYS\_PWRGD to Ensure That VDD\_INT is Restored

Voltage regulators commonly have a power good output which can be directly connected to the SYS\_PWRGD input of the processor. However, it is the user's responsibility to make sure that when the power good output of the regulator is asserted VDD\_INT has been restored to within the operating conditions specified in the processor's data sheet. If the regulator's power good output asserts before VDD\_INT has been restored to within the operating conditions specified in the processor's data sheet then the power good counter must be used to ensure that VDD\_INT has been restored to within specifications.

When the SYS\_PWRGD signal is used to indicate VDD\_INT is restored it is suggested that DPM\_PGCNTR.CNT be left at its default setting. The DPM then waits until the default DPM\_PGCNTR.CNT setting is expired and SYS\_PWRGD is asserted before kicking off the boot process.

## DPM Event Control

The DPM event is triggered when an enabled wake-up is asserted. DPM bus errors are generated when a misaligned access to a registers occurs or when an attempt is made to access unused DPM address space or a write protected register.

### DPM Events

The DPM event interrupt is triggered when any bit in DPM\_WAKE\_STAT is set. This indicates that an enabled wake-up was asserted. The DPM event interrupt will stay active until the user clears any bits that are set in DPM\_WAKE\_STAT.

### DPM Errors

The DPM will generate a bus error if a read or write transaction is attempted to an unused address within the DPM address range or if a misaligned access is made to an existing DPM register. In addition to the bus error DPM\_STAT.ADDRERR will be set.

If a write to a write protected DPM register is attempted a bus error will also be generated. In addition, DPM\_STAT.LWERR will be set.

## Configuring DPM DEEP SLEEP Mode

The DPM DEEP SLEEP mode gates all core and system clocks in order to save power.

### *PREREQUISITE:*

DEEP SLEEP can be entered from any state in which software can run. Reading `DPM_STAT.CURMODE` shows what the current power mode is. Clocks do not stop immediately after entry to DEEP SLEEP is requested, but no further action is needed to guarantee that the transition happens. Cores need to be idle in order for clocks are shut down.

1. Read `DPM_STAT` and `CGU_STAT`
2. If `DPM_STAT.CURMODE = FULL ON`, wait for `CGU_STAT.PLLBP = 0`, `CGU_STAT.PLOCK = 1` and `CGU_STAT.CLKSALGN = 0`.
3. If `DPM_STAT.CURMODE = ACTIVE` with PLL Disabled, wait for `CGU_STAT.PLEN = 0`
4. Enable the DPM Event interrupt to wake up the desired core in order to exit idle after DEEP SLEEP.
5. Set `DPM_WAKE_POL` wake-up source bits (`WSn`) to the desired polarity.
6. Enable the desired wake-up sources in `DPM_WAKE_EN`.
7. Set `DPM_CTL.DEEPSLEEP`
8. Clear all pending core transactions (this is done with an `SSYNC` instruction in Blackfin), DMA transactions, and interrupts.
9. Go to idle in all cores.

### *RESULT:*

The DPM is now configured to DEEP SLEEP mode and can be woken by asserting any of the enabled wakeup sources.

## Configuring DPM HIBERNATE Mode

The HIBERNATE mode allows `VDD_INT` to be shut off in order to save power.

### *PREREQUISITE:*

HIBERNATE can be entered from any DPM state in which software can be run. Reading `DPM_STAT.CURMODE` shows what the current power mode is. Make sure to save any data that needs to be preserved to the `DPM_RESTOREn` registers or to external memory before placing the processor into HIBERNATE mode. The following steps should be performed in code running from L1 memory on Blackfin processors.

1. Set `DPM_WAKE_POL` wake-up source bits (`WSn`) to the desired polarity.
2. Enable the desired wake-up sources in `DPM_WAKE_EN`.
3. Write to `DPM_HIB_DIS` if any blocks not on the `VDD_INT` domain need to be disabled.

*ADDITIONAL INFORMATION:* Note that `DPM_HIB_DIS` may not exist on your processor if there are no blocks on domains other than `VDD_INT` that are capable of being disabled during hibernate.

4. Write the power good count value to `DPM_PWRGDCNT.CNT`
5. Clear all pending core transactions (this is done with an `SSYNC` instruction in Blackfin), DMA transactions, and interrupts.
6. Set the `DPM_CTL.HIBERNATE` bit

*RESULT:*

The DPM is now configured to HIBERNATE mode.

## ADSP-BF60x Wake-Up Sources

The table below shows the HIBERNATE and DEEP SLEEP wake-up sources for the ADSP-BF60x.

The first column shows which wake-up source bit (`WSn`) is used in the `DPM_WAKE_EN`, `DPM_WAKE_POL`, and `DPM_WAKE_STAT` registers. The Assigned Source column shows which peripheral or pin source is assigned to the `WSn` bit. Peripherals in parentheses mean that the source can either be used as a GPIO wake-up or as the specific peripheral wake-up listed. The DEEP SLEEP column indicates whether or not the wake-up source can wake the processor from DEEP SLEEP. The HIBERNATE column indicates whether or not the wake-up source can wake the processor from HIBERNATE.

**Table 5-5:** ADSP-BF60x HIBERNATE and DEEP SLEEP Wake-up Sources

| DPM_WAKE_EN,<br>DPM_WAKE_POL, &<br>DPM_WAKE_STAT Bit | Assigned Source | DEEP SLEEP? | HIBERNATE? |
|------------------------------------------------------|-----------------|-------------|------------|
| WS0                                                  | PA_15           | Yes         | Yes        |
| WS1                                                  | PB_15           | Yes         | Yes        |
| WS2                                                  | PC_15           | Yes         | Yes        |
| WS3                                                  | PD_06           | Yes         | Yes        |
| WS4                                                  | PE_12           | Yes         | Yes        |

**Table 5-5:** ADSP-BF60x HIBERNATE and DEEP SLEEP Wake-up Sources (Continued)

| DPM_WAKE_EN,<br>DPM_WAKE_POL, &<br>DPM_WAKE_STAT Bit | Assigned Source                                           | DEEP SLEEP? | HIBERNATE? |
|------------------------------------------------------|-----------------------------------------------------------|-------------|------------|
| WS5                                                  | PG_04 (CAN0_RX)                                           | Yes         | Yes        |
| WS6                                                  | PG_13                                                     | Yes         | Yes        |
| WS7                                                  | USB<br>(DPM_WAKE_POL.WS<br>7 must be set to 1 for<br>USB) | No          | Yes        |
| WS30: WS8                                            | RESERVED                                                  | NA          | NA         |

## ADSP-BF60x Clock Buffer Disable Bit Assignments

The table below shows the clock buffers that may be disabled on ADSP-BF60x.

The first column shows which system clock buffer disable bit (SCBF<sub>n</sub>) is used in the DPM\_SCBF\_DIS register. The Assigned Clock column shows which clock buffer is assigned to the SCBF<sub>n</sub> bit.

**Table 5-6:** ADSP-BF60x Bit Assignments for DPM\_SCBF\_DIS

| DPM_SCBF_DIS Bit | Assigned Clock |
|------------------|----------------|
| SCBF0            | SCLK0          |
| SCBF1            | SCLK1          |
| SCBF2            | DCLK           |
| SCBF3            | OUTCLK         |

## ADSP-BF60x Hibernate Disable Bit Assignments

The table below shows the functional units that may be disabled during hibernate on ADSP-BF60x processors.

The first column shows which hibernate disable bit (HD<sub>n</sub>) is used in the DPM\_HIB\_DIS register. The functional unit column shows which functional unit is assigned to the HD<sub>n</sub> bit to allow disabling upon entering hibernate.

**Table 5-7:** ADSP-BF60x Bit Assignments for DPM\_HIB\_DIS

| DPM_SCBF_DIS Bit | Functional Unit           |
|------------------|---------------------------|
| HD0              | System crystal oscillator |
| HD7 : HD1        | Reserved                  |

## DPM Register Descriptions

Dynamic Power Management (DPM) contains the following registers.

**Table 5-8:** DPM Module Registers

| Name               | Description                              |
|--------------------|------------------------------------------|
| DPM_CTL            | Control Register                         |
| DPM_STAT           | Status Register                          |
| DPM_CCBF_DIS       | Core Clock Buffer Disable Register       |
| DPM_CCBF_EN        | Core Clock Buffer Enable Register        |
| DPM_CCBF_STAT      | Core Clock Buffer Status Register        |
| DPM_CCBF_STAT_STKY | Core Clock Buffer Status Sticky Register |
| DPM_SCBF_DIS       | System Clock Buffer Disable Register     |
| DPM_WAKE_EN        | Wakeup Enable Register                   |
| DPM_WAKE_POL       | Wakeup Polarity Register                 |
| DPM_WAKE_STAT      | Wakeup Status Register                   |
| DPM_HIB_DIS        | Hibernate Disable Register               |
| DPM_PGCNTR         | Power Good Counter Register              |
| DPM_RESTOREn       | Restore n Register                       |

## Control Register

The DPM\_CTL register controls sleep modes selections and PLL operations of the DPM. A write protect feature permits locking out changes to this register.

### DPM\_CTL: Control Register - R/W

Reset = 0x0000 0000

**Figure 5-2:** DPM\_CTL Register Diagram

**Table 5-9:** DPM\_CTL Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                     |

## Status Register

The DPM\_STAT register indicates error status for DPM operations and indicates the current and previous DPM modes.

### DPM\_STAT: Status Register - R/W

Reset = 0x0000 0001

**Figure 5-3:** DPM\_STAT Register Diagram

**Table 5-10:** DPM\_STAT Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                            |
|---------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19      | PLLCFGERR | PLL Configuration Error.<br>The DPM_STAT.PLLCFGERR bit indicates that either the DPM_CTL.PLLBPST bit and DPM_CTL.PLLBPCL bit have been set (=1) simultaneously or the DPM_CTL.PLLBPST has been set while the DPM is in full on mode or while the DPM is entering full on mode (DPM_CTL.PLLBPCL=1). |
|         |           | 0 No Status                                                                                                                                                                                                                                                                                        |
|         |           | 1 PLL Configuration Error                                                                                                                                                                                                                                                                          |
| 18      | HVBSYERR  | HV Busy Error.<br>The DPM_STAT.HVBSYERR bit indicates that a read access of DPM_WAKE_STAT or DPM_RESTOREn occurred during restore of DPM LV from DPM HV                                                                                                                                            |
|         |           | 0 No Status                                                                                                                                                                                                                                                                                        |
|         |           | 1 HV Busy Error                                                                                                                                                                                                                                                                                    |

**Table 5-10:** DPM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17      | LWERR    | Lock Write Error.<br>The DPM_STAT.LWERR bit indicates an attempt to write to a locked DPM register while the global lock bit is set (SPU_CTL_GLCK bit =1).                                                                                                                                           |
|         |          | 0                      No Status                                                                                                                                                                                                                                                                     |
|         |          | 1                      Lock Write Error                                                                                                                                                                                                                                                              |
| 16      | ADDRERR  | Address Error.<br>The DPM_STAT.ADDRERR bit indicates either an attempted read or write access to an address in the DPM MMR space that are not implemented addresses, an attempted write access to a DPM read only register, or a read or write access to a non aligned address in the DPM MMR space. |
|         |          | 0                      No Status                                                                                                                                                                                                                                                                     |
|         |          | 1                      Address Error                                                                                                                                                                                                                                                                 |
| 9       | HVBSY    | HV Busy.<br>The DPM_STAT.HVBSY bit indicates whether the DPM HV unit is ready (has completed all transactions) or is busy (transfers from HV have not yet completed).                                                                                                                                |
|         |          | 0                      Ready                                                                                                                                                                                                                                                                         |
|         |          | 1                      Busy                                                                                                                                                                                                                                                                          |
| 8       | CCLKDIS  | Core Clock(s) Disabled.<br>The DPM_STAT.CCLKDIS bit indicates whether or not one or more of the core clocks is disabled.                                                                                                                                                                             |
|         |          | 0                      No Status                                                                                                                                                                                                                                                                     |
|         |          | 1                      Clock (1 or more) Disabled                                                                                                                                                                                                                                                    |

**Table 5-10:** DPM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                  |

Wakeup Enable Register

The DPM\_WAKE\_EN register enables the wakeup event sources for exiting deep sleep mode. The number of wakeup sources varies with the processor design, with bit 0 corresponding to wakeup source 0, bit 1 corresponding to wakeup source 1, and so on. This register includes a write protection lock. For information about wakeup source assignments, see the DPM Wakeup Sources topic.

## Restore n Register

The DPM\_RESTOREn registers are general-purpose registers that the DPM preserves during hibernate mode and restores on exit from hibernate. The usage of these registers is application specific and does not affect DPM operations. For more information about using the DPM\_RESTOREn registers, see the programming model.

DPM\_RESTOREn: Restore n Register - R/W

## 6 Core Timers

Each processor core has its own dedicated timer. The core timer is clocked by the internal processor clock and is typically used as a system tick clock for generating periodic operating system interrupts.

### NOTE:

The core timer stops counting when there is an emulation event. The emulation event is controlled by the SDU (System Debug Unit). Please refer to the SDU chapter for more details on this.

## Core Timer Features

The core timer is a programmable 32-bit interval timer which can generate periodic interrupts. Unlike other peripherals, the core timer resides inside the Blackfin core and runs at the core clock (CCLK) rate. Core timer features include:

- 32-bit timer with 8-bit prescaler
- Operates at core clock (CCLK) rate
- Dedicated high-priority interrupt channel
- Single-shot or continuous operation

## TMR Register List

The core timer (TMR) is a programmable 32-bit interval timer, which can generate periodic interrupts. Unlike other peripherals, the core timer resides inside the processor core and runs at the core clock (CCLK) rate. A set of registers govern TMR operations. For more information on TMR functionality, see the TMR register descriptions.

**Table 6-1:** TMR Module Registers

| Name    | Description            |
|---------|------------------------|
| TCNTL   | Timer Control Register |
| TPERIOD | Timer Period Register  |
| TSCALE  | Timer Scale Register   |

**Table 6-1:** TMR Module Registers (Continued)

| Name   | Description          |
|--------|----------------------|
| TCOUNT | Timer Count Register |

Block Diagram

The following figure shows the core timer block diagram.

**Figure 6-1:** Core Timer Block Diagram

External Interfaces

The core timer does not directly interact with any pins of the chip.

Internal Interfaces

The core timer is accessed through the 32-bit register access bus (RAB). The module is clocked by the core clock CCLK. The timer’s dedicated interrupt request is a higher priority than requests from all other peripherals.

Timer Operation

The software should initialize the TCOUNT register before the timer is enabled. The TCOUNT register can be written directly, but writes to the TPERIOD register are also passed through to TCOUNT.

When the timer is enabled by setting the TMREN bit in the core timer control register (TCNTL), the TCOUNT register is decremented once every time the prescaler TSCALE expires, that is, every TSCALE + 1 number of CCLK clock cycles. When the value of the TCOUNT register reaches 0, an interrupt is generated and the TINT bit is set in the TCNTL register.

If the TAUTORLD bit in the TCNTL register is set, then the TCOUNT register is reloaded with the contents of the TPERIOD register and the count begins again. If the TAUTORLD bit is not set, the timer stops operation.

The core timer can be put into low power mode by clearing the TMPWR bit in the TCNTL register. Before using the timer, set the TMPWR bit. This restores clocks to the timer unit. When TMPWR is set, the core timer may then be enabled by setting the TMREN bit in the TCNTL register.

**NOTE:** Hardware behavior is undefined if TMREN is set when TMPWR = 0.

## Interrupt Processing

The timer's dedicated interrupt request is a higher priority than requests from all other peripherals. The request goes directly to the core event controller (CEC) and does not pass through the system event controller (SEC). Therefore, the interrupt processing is also completely in the CCLK domain.

**NOTE:** The core timer interrupt request is edge-sensitive and cleared by hardware automatically as soon as the interrupt is serviced.

The TINT bit in the TCNTL register indicates that an interrupt has been generated. Note that this is not a WIC bit. Write a 0 to clear it. However, the write is optional. It is not required to clear interrupt requests. The core time module doesn't provide any further interrupt enable bit. When the timer is enabled, interrupts can be masked in the CEC controller.

## TMR Register Descriptions

Core Timer (TMR) contains the following registers.

**Table 6-2:** TMR Module Registers

| Name    | Description            |
|---------|------------------------|
| TCNTL   | Timer Control Register |
| TPERIOD | Timer Period Register  |
| TSCALE  | Timer Scale Register   |
| TCOUNT  | Timer Count Register   |

# Timer Control Register

The TCNTL register functions as the TMR control and status register.

TCNTL: Timer Control Register - R/W

Reset = 0x0000 0000

| 3       | INT      | Interrupt Status (sticky).<br>The TCNTL . INT bit indicates the status of the timer generated interrupt, which is generated when the TCOUNT value decrements to 0. This bit is sticky, remaining set until cleared.         |
|         |          | 0 No Interrupt Pending                                                                                                                                                                                                      |
|         |          | 1 Pending Interrupt                                                                                                                                                                                                         |
| 2       | AUTORLD  | Auto Reload Enable.<br>The TCNTL . AUTORLD bit enables the TMR to automatically reload the TCOUNT register from the TPERIOD register when the count expires. If disabled, the timer stops operation when the count expires. |
|         |          | 0 Disable Auto Reload                                                                                                                                                                                                       |
|         |          | 1 Enable Auto Reload                                                                                                                                                                                                        |

**Table 6-3:** TCNTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | EN       | Timer Enable.<br>The TCNTL.EN bit enables TMR operation, starting the count at the value in the TCOUNT register and decrementing this value each time the prescaler (TSCALE) time expires.                                                                         |
|         |          | 0      Disable Timer                                                                                                                                                                                                                                               |
|         |          | 1      Enable Timer                                                                                                                                                                                                                                                |
| 0       | PWR      | Low Power Mode Select.<br>The TCNTL.PWR bit selects active mode or low power mode for TMR operation. When in low power mode, clocks to the TMR are disabled. Before enabling the timer (TCNTL.EN = 1), put the timer in active mode (restoring clocks to the TMR). |
|         |          | 0      Low Power Mode                                                                                                                                                                                                                                              |
|         |          | 1      Active Mode                                                                                                                                                                                                                                                 |

## Timer Period Register

The TPERIOD register holds the timer period. When the processor writes the TPERIOD register, the TMR automatically writes the value to the TCOUNT register also. When count auto reload is enabled (TCNTL.AUTORLD = 1), the TMR automatically reloads the TCOUNT register with the value in TPERIOD when the counter expires. Note that writes to TPERIOD are ignored when the timer is running.

**TPERIOD: Timer Period Register - R/W**

Reset = 0x0000 0000

**Figure 6-3:** TPERIOD Register Diagram

Table 6-4: TPERIOD Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                     |
|---------|----------|-----------------------------------------------------------------------------|
| 31:0    | PERIOD   | Timer Period Value.<br>The TPERIOD.PERIOD bits hold the timer period value. |

Timer Scale Register

The TSCALE register stores the scaling value that is one core clock (CCLK) cycle less than the number of cycles between each decrement of the timer count (TCOUNT). For example, if the value in the TSCALE register is 0, the TCOUNT register decrements once for every CCLK cycle. If the TSCALE value is 1, the TCOUNT decrements once every two CCLK cycles.

TSCALE: Timer Scale Register - R/W  
Reset = 0x0000 0000

Table 6-5: TSCALE Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                          |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | SCALE    | Timer Scaling Value.<br>The TSCALE.SCALE bits hold a scaling factor, relating CCLK cycles to the rate that the count decrements. |

Timer Count Register

The TCOUNT register holds the current count for the TMR. Typically, this count is initially load with a write to the TPERIOD register, because the TMR automatically copies the value written to the TPERIOD register and writes the value to the TCOUNT register. The TCOUNT register can be written directly. When the timer is running, the TCOUNT value decrements once every TSCALE + 1 core clock (CCLK) cycles. When the value in TCOUNT reaches 0, the TMR generates an interrupt and sets the TCNTL.INT bit. Note that writes to TCOUNT are ignored when the timer is running.

TCOUNT: Timer Count Register - R/W

Reset = 0x0000 0000

Table 6-6: TCOUNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                 |
|---------|----------|-------------------------------------------------------------------------|
| 31:0    | CNT      | Timer Count.<br>The TCOUNT.CNT bits hold the current timer count value. |

# 7 System Event Controller (SEC)

System event management is the responsibility of the system event controller (SEC). The SEC manages the configuration of all system event sources as well as the propagation of system events to all connected cores and the system fault interface.

## SEC Features

The following list describes the system event controller features.

- Comprehensive system event source management including interrupt enable, fault enable, prioritization, core mapping and source grouping.
- Fault management including fault action configuration, time out, external indication, and system reset.
- Determinism where all system events have the same propagation delay and provide unique identification of a specific system event source.
- Distributed programming model where each system event source control and all status fields are completely independent of all others.
- Slave Control Port which provides access to all SEC registers for configuration, status, and interrupt/fault service model.
- Global locking supports a register level protection model to prevent writes to “locked” registers.

## SEC Functional Description

The following sections provide a functional description of the SEC.

### SEC Register List

The system event controller (SEC) manages the system interrupt and system fault sources. The SEC also provides all system interrupt and fault sources control features, such as enable/disable, prioritization, and active/pending source status. On multi-core processors, the SEC provides connected core(s) and fault management with source pending and active indication. For more information on SEC functionality, see the SEC register descriptions.

**Table 7-1:** SEC Module Registers

| Name           | Description                               |
|----------------|-------------------------------------------|
| SEC_CCTLn      | SCI Control Register n                    |
| SEC_CSTATn     | SCI Status Register n                     |
| SEC_CPNDn      | Core Pending Register n                   |
| SEC_CACTn      | SCI Active Register n                     |
| SEC_CPMSKn     | SCI Priority Mask Register n              |
| SEC_CGMSKn     | SCI Group Mask Register n                 |
| SEC_CPLVLn     | SCI Priority Level Register n             |
| SEC_CSIDn      | SCI Source ID Register n                  |
| SEC_FCTL       | Fault Control Register                    |
| SEC_FSTAT      | Fault Status Register                     |
| SEC_FSID       | Fault Source ID Register                  |
| SEC_FEND       | Fault End Register                        |
| SEC_FDLY       | Fault Delay Register                      |
| SEC_FDLY_CUR   | Fault Delay Current Register              |
| SEC_FSRDLY     | Fault System Reset Delay Register         |
| SEC_FSRDLY_CUR | Fault System Reset Delay Current Register |
| SEC_FCOPP      | Fault COP Period Register                 |
| SEC_FCOPP_CUR  | Fault COP Period Current Register         |
| SEC_GCTL       | Global Control Register                   |
| SEC_GSTAT      | Global Status Register                    |
| SEC_RAISE      | Global Raise Register                     |
| SEC_END        | Global End Register                       |

**Table 7-1:** SEC Module Registers (Continued)

| Name       | Description               |
|------------|---------------------------|
| SEC_SCTLn  | Source Control Register n |
| SEC_SSTATn | Source Status Register n  |

## ADSP-BF60x Interrupt List

**Table 7-2:** ADSP-BF60x Interrupt List

| Description                                    | ID | DMA Channel | Sensitivity |
|------------------------------------------------|----|-------------|-------------|
| SEC0 Error                                     | 0  |             | LEVEL       |
| CGU0 Event                                     | 1  |             | PULSE/EDGE  |
| WDOG0 Expiration                               | 2  |             | LEVEL       |
| WDOG1 Expiration                               | 3  |             | LEVEL       |
| L2CTL0 ECC Error                               | 4  |             | LEVEL       |
| Core 0 Double Fault                            | 6  |             | PULSE/EDGE  |
| Core 1 Double Fault                            | 7  |             | PULSE/EDGE  |
| Core 0 Hardware Error                          | 8  |             | PULSE/EDGE  |
| Core 1 Hardware Error                          | 9  |             | PULSE/EDGE  |
| Core 0 Unhandled NMI or L1 Memory Parity Error | 10 |             | PULSE/EDGE  |
| Core 1 Unhandled NMI or L1 Memory Parity Error | 11 |             | PULSE/EDGE  |
| TIMER0 Timer 0                                 | 12 |             | LEVEL       |
| TIMER0 Timer 1                                 | 13 |             | LEVEL       |
| TIMER0 Timer 2                                 | 14 |             | LEVEL       |
| TIMER0 Timer 3                                 | 15 |             | LEVEL       |

**Table 7-2:** ADSP-BF60x Interrupt List (Continued)

| Description                    | ID | DMA Channel | Sensitivity |
|--------------------------------|----|-------------|-------------|
| TIMER0 Timer 4                 | 16 |             | LEVEL       |
| TIMER0 Timer 5                 | 17 |             | LEVEL       |

| Description | ID  | DMA Channel | Sensitivity |
|-------------|-----|-------------|-------------|
| SWU1 Event  | 134 |             | LEVEL       |
| SWU2 Event  | 135 |             | LEVEL       |
| SWU3 Event  | 136 |             | LEVEL       |
| SWU4 Event  | 137 |             | LEVEL       |
| SWU5 Event  | 138 |             | LEVEL       |
| SWU6 Event  | 139 |             | LEVEL       |

## **SEC Definitions**

The following definitions are used in describing the event controller.

### **System Events**

System source indications including interrupts and faults

### **System Source**

Point of origin of system event

### **SID (Identification, unique)**

Source numeric identifier for each system source connected to the SEC

### **SSI**

SEC Source Interface, system event source control and status sub-block of the SEC

### **SCI**

SEC Core Interface, core interface sub-block of the SEC

### **SPR**

SEC prioritizer determines the highest priority pending interrupt and the highest priority active interrupt and provides them in the appropriate registers of the SCI for the prioritization and nesting model of the SCI

### **SFI**

SEC Fault Interface, fault management sub-block of the SEC

## **SEC Block Diagram**

System sources connect to the SEC through the SSI. Each core has a dedicated SCI. The SFI provides fault action connections to the rest of the system.

Figure 7-1: System Even Controller Block Diagram

SFI Block Diagram

The SFI manages fault events and associated actions. The fault management support provided in the SEC is intended to help satisfy the safety requirements of various applications. The SSI provides the highest priority pending source that is enabled as a fault. The SFI captures this value and enables a countdown and, once the countdown expires, the prescribed action is taken.

Figure 7-2: SFI Overview Block Diagram

## SCI Block Diagram

The SCI manages communication between the corresponding core and the SEC. The SPR of the SCI receives pending, active, and priority information from the SSI for each system event source assigned to this SCI. The SPR determines the highest priority pending system event and the SCI determines whether it will propagate to the core. The SCI maintains the coherency for the system event service model implemented on the connected core.

**Figure 7-3:** SCI Overview Block Diagram

## SSI Block Diagram

The SSI manages all of the system event sources. The status of each source is maintained in the corresponding SSTAT register and the control of each source is managed by the corresponding SCTL register. A pending and enabled event passes its indication and priority to the SCI to which it is assigned for further processing.

**Figure 7-4:** SSI Overview Block Diagram

## SEC Architectural Concepts

This section describes SEC architectural features supporting interrupt acknowledge, priority levels, grouping, flow, and error management.

### System Interrupt Acknowledge

System interrupt acknowledge is defined as the core providing indication that it has acquired the SID of the interrupt last issued by the SEC. The SEC core interface option allows for this to be generated by either of the following.

- Slave port write to the CSIDn register.
- Assertion of input ACK signal (generated by connected core)

### System Interrupt Groups

System sources can be assigned to groups using the SCTLn.GRP field. Source groups allow fast context switching for system interrupts at each SCI. The CGMSK register allows quick masking of unlimited size interrupt groups with a single write operation.

### System Interrupt Flow

An enabled and asserted system interrupt source is latched at the SSI and routed to the appropriate SCI based on the SCTLn.CTG bit field setting. The SEC prioritizer determines the highest priority pending system interrupt and the SCI updates the CPND register with the SID and PRIO bit field values. The SCI compares the CPND register value against the highest priority active source in the CACT register).

The `CPLVLM` register determines how many of the MSBs are used in the comparison while the `CPMSKm` and `CGMSK` registers determine which pending interrupt sources participate. If `CPND` register value is a higher priority (lower value) than that of the `CACT` register from the comparison based on `CPLVL` register, the system interrupt output is asserted and the `CSID` register is updated with the `SID` field of the `CPND` register and forwarded to the connected core.

After the core provides an interrupt acknowledgment (MMR write of the `CSID` register or the core version of the `CSID` register), the interrupt source is set active (`SCTL.ACT==1`) until the service is complete by a write of the same `SID` value to `END`.

#### Example Flow – Single Interrupt

1. The SEC compares the `CPND` register value to the `CACT` register value, if the interrupt in the `CPND` register is higher priority, continue.
2. The SEC copies the `CPND` register value to the `CSID` register and asserts the `INT` signal.
3. The core reads the `CSID` register (or core version).
4. The core writes to the `CSID` register (or core version, asserts the `ACK` signal).
5. The SEC de-asserts the `INT` signal and clears the `PND` bit and sets the `ACT` bit in the `SSTAT` register of the source going active.
6. The core writes the `SID` of the active interrupt to the `END` register.
7. The SEC clears the `ACT` bit in the `SSTAT` register of the source being ended.

#### Example Flow – Interrupt Nesting (Interrupt A is Lower Priority and Occurs Earlier than Interrupt B)

1. The SEC compares the `CPND` (A) register value to the `CACT` register and if the interrupt in the `CPND` register is a higher priority, continue.
2. The SEC copies `CPND` (A) register to the `CSID` register and asserts the `INT` signal.
3. The core reads the `CSID` (A) register (or core version).
4. The core writes to the `CSID` register (or core version, asserts the `ACK` signal).
5. The SEC de-asserts the `INT` signal and clears the `PND` bit and sets the `ACT` bit in the `SSTAT` register of the source (A) going active.
6. The SEC compares the `CPND` (B) register value to the `CACT` (A) register value. If the `CACT` (A) register value is a higher priority, continue.
7. The SEC copies the `CPND` (B) register value to `CSID` register and asserts the `INT` signal.
8. The core reads the `CSID` (B) register (or core version).
9. The core writes to the `CSID` register (or core version, asserts the `ACK` signal).

10. The SEC de-asserts the `INT` signal and clears the `PND` bit and sets the `ACT` bit in the `SSTAT` register of the source (B) going active.
11. The core writes the `SID` of the active interrupt (B) to the `END` register.
12. The SEC clears the `ACT` bit in the `SSTAT` register of the source (B) being ended.
13. The core writes the `SID` of the active interrupt (A) to the `END` register.
14. The SEC clears the `ACT` bit in the `SSTAT` register of the source (A) being ended.

## **SEC Error**

An SEC error (`GSTAT.ERR`) is included as a system source input to the SEC to allow for handling the error as an interrupt or fault.

## **SEC Programming Model**

Implementing a system interrupt service model using the SEC requires, at a minimum, proper configuration of a system interrupt source (for example a peripheral or DMA), core interrupt/event service model, and the SEC. The core must be configured for response to system interrupts from the SEC. The SEC must be configured to enable and map the system interrupt source to the correct SCI and to forward interrupts to the connected core.

The system interrupt source must be configured to generate interrupt assertions. Alternatively, software triggering may be used for interrupt assertion. Software driven interrupts are generated by writing the source ID of the interrupt to be triggered to the `RAISE` register.

## **Programming Concepts**

The following list provides the basic programming concepts necessary for configuring the system event controller.

- Configuring an SSI as a system interrupt for a specific core.
- Configuring an SCI to provide system interrupts to the connected core.
- Configuring an SSI as a system fault.
- Configuring the SFI to manage system faults.

## **Programming Examples**

This section provides example programming tasks that are typical for SEC usage.

## Configuring a System Source to Interrupt a Core

1. Write to the GCTL register to enable the SEC.
2. Write to the CCTL register of the specific SCI to enable interrupts to be sent to core.
3. Write to the SCTL register of specific source to enable the source as an interrupt and set the core target field to map the source to the appropriate SCI.

## Configuring a System Source as a Fault

1. Write to the GCTL register to enable the SEC.
2. Write to the FCTL register to configure specific fault actions.
3. Optionally write to the FDELAY bit field to specify fault delay.
4. Write to the SCTL register of a specific source to enable the source as a fault.

## SEC Register Descriptions

System Event Controller (SEC) contains the following registers.

**Table 7-3:** SEC Module Registers

| Name       | Description                   |
|------------|-------------------------------|
| SEC_CCTLn  | SCI Control Register n        |
| SEC_CSTATn | SCI Status Register n         |
| SEC_CPNDn  | Core Pending Register n       |
| SEC_CACTn  | SCI Active Register n         |
| SEC_CPMSKn | SCI Priority Mask Register n  |
| SEC_CGMSKn | SCI Group Mask Register n     |
| SEC_CPLVLn | SCI Priority Level Register n |
| SEC_CSIDn  | SCI Source ID Register n      |
| SEC_FCTL   | Fault Control Register        |
| SEC_FSTAT  | Fault Status Register         |

**Table 7-3:** SEC Module Registers (Continued)

| Name           | Description                               |
|----------------|-------------------------------------------|
| SEC_FSID       | Fault Source ID Register                  |
| SEC_FEND       | Fault End Register                        |
| SEC_FDLY       | Fault Delay Register                      |
| SEC_FDLY_CUR   | Fault Delay Current Register              |
| SEC_FSRDLY     | Fault System Reset Delay Register         |
| SEC_FSRDLY_CUR | Fault System Reset Delay Current Register |
| SEC_FCOPP      | Fault COP Period Register                 |
| SEC_FCOPP_CUR  | Fault COP Period Current Register         |
| SEC_GCTL       | Global Control Register                   |
| SEC_GSTAT      | Global Status Register                    |
| SEC_RAISE      | Global Raise Register                     |
| SEC_END        | Global End Register                       |
| SEC_SCTLn      | Source Control Register n                 |
| SEC_SSTATn     | Source Status Register n                  |

## SCI Control Register n

The SEC control register (SEC\_CCTLn) contains SCI control bits for all system sources.

**SEC\_CCTLn: SCI Control Register n - R/W**

Reset = 0x0000 0000

**Figure 7-5:** SEC\_CCTLn Register Diagram

**Table 7-4:** SEC\_CCTLn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                           |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | Lock.<br>If the global lock is enabled (SPU_CTL_GLCK bit =1) and the SEC_CCTLn.LOCK bit is enabled, the SEC_CCTLn register is read only.                                          |
|         |          | 0      Unlock                                                                                                                                                                     |
|         |          | 1      Lock                                                                                                                                                                       |
| 16      | NMIEN    | NMI Enable.<br>The SEC_CCTLn.NMIEN bit controls NMI propagation to the core. When the SEC_CCTLn.NMIEN bit is enabled, the SCI allows NMIs to propagate to the core for servicing. |
|         |          | 0      Disable                                                                                                                                                                    |
|         |          | 1      Enable                                                                                                                                                                     |
| 12      | WFI      | Wait For Idle.<br>When set, the SEC_CCTLn.WFI bit forces the SCI to wait for indication of core idle before the SCI resumes activity.                                             |
|         |          | 0      No Action                                                                                                                                                                  |
|         |          | 1      Wait for Idle                                                                                                                                                              |

**Table 7-4:** SEC\_CCTLn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | RESET    | Reset.<br>When set, the SEC_CCTLn.RESET bit resets all SCI registers to their default values.                                                                                                                                                                                        |
|         |          | 0                      No Action                                                                                                                                                                                                                                                     |
|         |          | 1                      Reset                                                                                                                                                                                                                                                         |
| 0       | EN       | Enable.<br>The SEC_CCTLn.EN bit controls operation of the SCI. Clearing the SEC_CCTLn.EN bit halts the execution of the SCI without resetting status registers. Setting the SEC_CCTLn.EN bit enables the SCI to begin or resume operation with the current configuration and status. |
|         |          | 0                      Disable                                                                                                                                                                                                                                                       |
|         |          | 1                      Enable                                                                                                                                                                                                                                                        |

SCI Status Register n

The SCI status register (SEC\_CSTATn) contains status bits, indicating the operational status of the SCI.

SEC\_CSTATn: SCI Status Register n - R/W

Reset = 0x0000 0000

**Figure 7-6:** SEC\_CSTATn Register Diagram

**Table 7-5:** SEC\_CSTATn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Core Pending Register n

The SCI pending interrupt register (SEC\_CPNDn) contains the source ID and priority of the highest priority pending interrupt detected by the SEC prioritizer.

SEC\_CPNDn: Core Pending Register n - R/NW

Reset = 0x0000 0000

Figure 7-7: SEC\_CPNDn Register Diagram

Table 7-6: SEC\_CPNDn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | PRIO     | Highest Pending IRQ Priority.<br>The SEC_CPNDn.PRIO indicates the priority value of the highest priority pending interrupt for core n.   |
| 7:0     | SID      | Highest Pending IRQ Source ID.<br>The SEC_CPNDn.SID identifies the source ID value of the highest priority pending interrupt for core n. |

SCI Active Register n

The SEC SCI active interrupt register (SEC\_CACTn) contains the source ID and priority of the highest priority active interrupt detected by the SEC prioritizer.

SEC\_CACTn: SCI Active Register n - R/NW

Reset = 0x0000 0000

Figure 7-8: SEC\_CACTn Register Diagram

**Table 7-7:** SEC\_CACTn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------|

|         |          | 1                      Lock                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2:0     | PLVL     | <p>Priority Levels.</p> <p>The SEC_CPLVLn.PLVL field serves to divide the total number of interrupt priority levels into sub-levels. The sub-level priority resolution provides the tie breaker for simultaneously pending interrupts assigned to the same interrupt level. The sub-level priority value specifies the number of MSBs (minus 1) designated to interrupt levels, while the remaining LSBs are designated for sub-level specification. For example, if the SEC_CPLVLn.PLVL field is set to two, the result is four priority levels are specified, because only the two MSBs are used for preemption evaluation. The remaining bits of the priority setting are used for sub-level prioritization.</p> <p>000 = 1 MSB (2 priority levels)</p> <p>...</p> <p>111 = 8 MSBs (256 priority levels)</p> |

## SCI Source ID Register n

The SCI source ID register (SEC\_CSIDn) contains the source ID of the interrupt last issued to core n. The SEC\_CSIDn register value is loaded by the SCI when a system interrupt indication is sent to core n. The SCI does not change the SEC\_CSIDn until after the interface receives an interrupt acknowledge from core n. Writing to the SEC\_CSIDn register generates an interrupt acknowledge, but does not update the value in the register.

SEC\_CSIDn: SCI Source ID Register n - R/W

Reset = 0x0000 0000

Figure 7-12: SEC\_CSIDn Register Diagram

Table 7-11: SEC\_CSIDn Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | SID      | Source ID.              |

Fault Control Register

The SEC fault control register (SEC\_FCTL) contains fault control bits for all SEC channels.

SEC\_FCTL: Fault Control Register - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | Lock.<br>If the global lock is enabled (SPU_CTL_GLCK bit =1) and the SEC_FCTL.LOCK bit is enabled, the SEC_FCTL register is read only.                                                                                                                                                                                                                                                                        |
|         |          | 0                      UnLock                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1                      Lock                                                                                                                                                                                                                                                                                                                                                                                   |
| 13      | TES      | Trigger Event Select.<br>The SEC_FCTL.TES bit selects the event that directs the SEC to assert trigger output. In fault pending mode, the SEC asserts trigger output when a fault is pending. In fault active mode, the SEC asserts trigger output when a fault is active.                                                                                                                                    |
|         |          | 0                      Fault Active Mode                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1                      Fault Pending Mode                                                                                                                                                                                                                                                                                                                                                                     |
| 12      | CMS      | COP Mode Select.<br>The SEC_FCTL.CMS selects the SEC mode for handling fault input. In COP mode, the SEC toggles the COP pin to indicate that no fault is active and ceases toggling the pin to indicate that a fault is active. In fault mode, the SEC deasserts the fault pin (=0) and fault_b pin (=1) when no fault is active and asserts the fault pin (=1) and fault_b pin (=0) when a fault is active. |
|         |          | 0                      Fault Mode                                                                                                                                                                                                                                                                                                                                                                             |
|         |          | 1                      COP Mode                                                                                                                                                                                                                                                                                                                                                                               |
| 7       | FIEN     | Fault Input Enable.<br>The SEC_FCTL.FIEN bit enables the SEC the to sample fault input. If SEC_FCTL.FIEN is set (=1), a fault indication from an external device sets the SEC_FSTAT.ACT bit and SEC_FSID.FEXT bit.                                                                                                                                                                                            |
|         |          | 0                      Disable                                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 1                      Enable                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 7-12:** SEC\_FCTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | SREN     | System Reset Enable.<br>The SEC_FCTL.SREN bit enables the SEC to issue a system reset request when a fault becomes active.                                                                                                                                                                    |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                |
|         |          | 1      Enable                                                                                                                                                                                                                                                                                 |
| 5       | TOEN     | Trigger Output Enable.<br>The SEC_FCTL.TOEN bit enables the SEC to produce trigger output when a fault becomes active.                                                                                                                                                                        |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                |

## Fault Status Register

The SEC fault status register (SEC\_FSTAT) contains status bits for all SEC channels.

**SEC\_FSTAT: Fault Status Register - R/W**

Reset = 0x0000 0000

**Figure 7-14:** SEC\_FSTAT Register Diagram

**Table 7-13:** SEC\_FSTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10      | NPND     | Next Pending Fault.<br>The SEC_FSTAT.NPND bit indicates that one or more sources have signalled fault assertion, but the input has not yet triggered the fault pending detection in the SEC fault interace. The SEC sets the SEC_FSTAT.NPND bit when the fault interface detects assertion of any enabled fault source input, while either SEC_FSTAT.PND or SEC_FSTAT.ACT bits are set. The SEC clears the SEC_FSTAT.NPND bit when there are no fault sources waiting. |
|         |          | 0                      Not Pending                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 7-13:** SEC\_FSTAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |              |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| 9       | ACT      | Fault Active.<br>The SEC_FSTAT.ACT bit indicates that the SEC has received a fault source input, the current fault delay count (in the SEC_FDLY_CUR register) has expired, and the fault actions are enabled. The SEC also sets the SEC_FSTAT.ACT bit on fault input detection if the SEC_FCTL.FIEN bit is set. The SEC_FSTAT.ACT bit is cleared by writing the SEC_END.SID value of the asserted fault from SEC_FSID register to the SEC_FEND register.                                                                                                                                                                                                                                                                                                                                        |              |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | No Fault     |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Active Fault |
| 8       | PND      | Pending Fault.<br>The SEC_FSTAT.PND bit indicates a fault source has signalled a fault assertion to the SEC, but the SEC has not yet triggered the event actions due to delay selected with the SEC_FDLY register. The SEC fault interface sets the SEC_FSTAT.PND bit when the SEC_FSID is updated on assertion a fault source input. The SEC_FSTAT.PND bit is only set when the SEC_FSTAT.ACT bit is cleared. The SEC updates the SEC_FSID register with the SEC_END.SID value from the SEC_END register when the SEC_FSTAT.PND bit is set. The SEC_FSTAT.PND bit is cleared either by the SEC fault interface when the current delay count in the SEC_FDLY_CUR register expires or by writing the SEC_FSID.SID field value (indicates the ID of the asserted fault) to the SEC_FEND register. |              |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Not Pending  |

## Fault Source ID Register

The SEC fault source ID register (SEC\_FSID) contains a fault source ID and internal/external fields.

SEC\_FSID: Fault Source ID Register - R/NW

Reset = 0x0000 0000

Figure 7-15: SEC\_FSID Register Diagram

Table 7-14: SEC\_FSID Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | FEXT     | Fault External.<br>The SEC_FSID.FEXT bit indicates that the last active fault was asserted by an external device. The SEC sets the SEC_FSID.FEXT bit when the SEC_FSTAT register's SEC_FSTAT.ACT bit is set by the fault input pins. The SEC_FSID.FEXT bit is cleared when the SEC_FSTAT.ACT bit is set by an internal fault or when the external fault is ended. When the SEC_FSID.FEXT bit is set, the SEC_FSID.SID is cleared. |
|         |          | 0      Fault Internal                                                                                                                                                                                                                                                                                                                                                                                                             |
|         |          | 1      Fault External                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7:0     | SID      | Source ID.<br>The SEC_FSID.SID identifies the fault assertion detected by the SEC fault interface. The SEC loads the SEC_FSID.SID field value when a system fault indication is asserted. The SEC fault interface does not change the SEC_FSID.SID value until the fault is no longer pending or active, as indicated by the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit being cleared in the SEC_FSTAT register.                     |

Fault End Register

The SEC fault end register (SEC\_FEND) contains fault source ID and internal/external fields.

SEC\_FEND: Fault End Register - R/W

Reset = 0x0000 0000

|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | FEXT     | Fault External.<br>Setting the SEC_FEND.FEXT bit, when the SEC_FEND.SID field is cleared, clears an active fault from an external source.                                                                                                                          |
|         |          | 0      Fault Internal                                                                                                                                                                                                                                              |
|         |          | 1      Fault External                                                                                                                                                                                                                                              |
| 7:0     | SID      | Source ID.<br>The SEC_FEND.SID identifies a fault to be ended as indicated to the SEC by the core. The core loads the SEC_FEND.SID field value. If the SEC_FEND.SID value matches the SEC_FSID.SID value, the SEC_FSTAT.PND bit and SEC_FSTAT.ACT bit are cleared. |

Fault Delay Register

The SEC fault delay register (SEC\_FDLY) contains the number (SEC\_FDLY.COUNT field) of SCLK periods to delay from fault pending to fault active, when actions are enabled.

SEC\_FDLY: Fault Delay Register - R/W

Reset = 0x0000 0000

Figure 7-17: SEC\_FDLY Register Diagram

Table 7-16: SEC\_FDLY Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | COUNT    | Fault Delay.            |

Fault Delay Current Register

The SEC fault delay current register (SEC\_FDLY\_CUR) contains the active count (SEC\_FDLY\_CUR.COUNT field) in SCLK periods for the delay from fault pending to fault active, when actions are enabled. The count is loaded from the SEC\_FDLY register when a fault becomes pending (SEC\_FSTAT.PND bit is set). The SEC decrements the value in SEC\_FDLY\_CUR each SCLK cycle while the SEC\_FSTAT.PND bit is set.

SEC\_FDLY\_CUR: Fault Delay Current Register - R/NW

Reset = 0x0000 0000

Figure 7-18: SEC\_FDLY\_CUR Register Diagram

**Table 7-17:** SEC\_FDLY\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | COUNT    | Fault Delay.            |

## Fault System Reset Delay Register

The SEC fault system reset delay register (SEC\_FSRDLY) contains the number (SEC\_FSRDLY.COUNT field) of SCLK periods for the delay from a fault becoming active to system reset request assertion, if enabled.

**SEC\_FSRDLY: Fault System Reset Delay Register - R/W**

Reset = 0x0000 0000

**Figure 7-19:** SEC\_FSRDLY Register Diagram

**Table 7-18:** SEC\_FSRDLY Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 31:0    | COUNT    | Fault System Reset Delay. |

## Fault System Reset Delay Current Register

The SEC fault system reset delay current register (SEC\_FSRDLY\_CUR) contains the active count (SEC\_FSRDLY\_CUR.COUNT field) in SCLK periods for the delay from fault active to system reset assertion, if enabled. The count is loaded from the SEC\_FSRDLY register when a fault becomes active (SEC\_FSTAT.ACT bit is set). The SEC decrements the value in SEC\_FSRDLY\_CUR each SCLK cycle while the SEC\_FSTAT.ACT bit is set.

SEC\_FSRDLY\_CUR: Fault System Reset Delay Current Register - R/NW

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 31:0    | COUNT    | Fault System Reset Delay. |

Fault COP Period Register

The SEC fault COP period register (SEC\_FCOPP) contains the width value (count in SCLK cycles) for the high and low phase of the computer operating properly (COP) toggled output on the COP pin. Note that the actual high/low phase is value is the SEC\_FCOPP.COUNT programmed value plus 1.

SEC\_FCOPP: Fault COP Period Register - R/W

Reset = 0x0000 0000

Figure 7-21: SEC\_FCOPP Register Diagram

Table 7-20: SEC\_FCOPP Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | COUNT    | Fault COP Period.       |

## Fault COP Period Current Register

The SEC fault COP period current register (SEC\_FCOPP\_CUR) contains the active count (in SCLK periods) for the current phase (high or low) of the computer operating properly (COP) toggled output on the COP pin. The SEC loads the SEC\_FCOPP\_CUR register from the SEC\_FCOPP register when the SEC\_FCOPP\_CUR.COUNT field is cleared and the SEC is in COP mode (SEC\_FCTL.CMS bit =1). The SEC decrements the SEC\_FCOPP\_CUR count each SCLK cycle while SEC\_FCTL.CMS is set and the SEC\_FSTAT.ACT bit is not set.

SEC\_FCOPP\_CUR: Fault COP Period Current Register - R/NW

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | COUNT    | Fault COP Period.       |

## Global Control Register

The SEC global control register (SEC\_GCTL) provides register locking, reset, and, and enable for the SEC module.

**SEC\_GCTL: Global Control Register - R/W**

Reset = 0x0000 0000

**Figure 7-23:** SEC\_GCTL Register Diagram

**Table 7-22:** SEC\_GCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                             |

## Global Raise Register

The SEC global raise register (SEC\_RAISE) contains a source ID interrupt set to pending field (SEC\_RAISE.SID). When a source ID value is written to this field, the SEC raises the source's interrupt to pending.

SEC\_RAISE: Global Raise Register - R/W

Reset = 0x0000 0000

Figure 7-25: SEC\_RAISE Register Diagram

Table 7-24: SEC\_RAISE Register Fields

| Bit No. | Bit Name | Description/Enumeration       |
|---------|----------|-------------------------------|
| 7:0     | SID      | Source ID IRQ Set to Pending. |

Global End Register

The SEC global end register (SEC\_END) contains a source ID interrupt end service field (SEC\_END.SID). When a core has finished servicing an interrupt, the core writes the SEC\_END.SID field in the SEC\_END register. This write causes the SEC to clear the SEC\_SSTATn.ACT bit in the SEC\_SSTATn register of the corresponding interrupt.

SEC\_END: Global End Register - R/W

Reset = 0x0000 0000

Figure 7-26: SEC\_END Register Diagram

Table 7-25: SEC\_END Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | SID      | Source ID IRQ to End.   |

Source Control Register n

The SEC interrupt source control register (SEC\_SCTLn) contains control bits to configure the SEC interrupt sources for core n.

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 19:16   | GRP      | <p>Group Select.</p> <p>The <code>SEC_SCTLn.GRP</code> bits each select a specific group for the interrupt. Each system interrupt can be assigned to any combination of groups supported by the <code>SEC_SCTLn.GRP</code> field.</p> <p>For example, consider the situation where <code>SEC_SCTLn.GRP0</code> represents interrupt group 0, <code>SEC_SCTLn.GRP1</code> represents interrupt group 1, and so on. One group might be used for all enabled interrupts (for example, group 0) and an additional group might be used for all wakeup interrupts (for example, group 1). This approach supports a model of all interrupts and just the wakeup subset.</p> <p>Before going to idle or sleep, all non-wakeup interrupts can be masked off to allow only wakeup interrupts to be enabled for service. Selecting no group (all <code>SEC_SCTLn.GRP</code> bits = 0) places the interrupt source in the category of "ungrouped".</p> |                 |
| 15:8    | PRI0     | <p>Priority Level Select.</p> <p>The <code>SEC_SCTLn.PRI0</code> bits sets the relative priority for an interrupt request. A pending interrupt request forwards its <code>SEC_SCTLn.PRI0</code> value to the SEC core interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                 |
| 4       | ERREN    | <p>Error Enable.</p> <p>The <code>SEC_SCTLn.ERREN</code> bit permits the <code>SEC_SSTATn.ERR</code> status bit to be set on error detection. If <code>SEC_SCTLn.ERREN</code> is cleared, no errors are detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |

## Source Status Register n

The SEC interrupt source status register (SEC\_SSTATn) contains bits indicating the status of the corresponding interrupt source n. An interrupt source may be: pending, active, active and pending, or neither pending nor active.

**SEC\_SSTATn: Source Status Register n - R/W**

Reset = 0x0000 0000

**Figure 7-28:** SEC\_SSTATn Register Diagram

**Table 7-27:** SEC\_SSTATn Register Fields

| Bit No. | Bit Name      | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |   |           |   |               |
|---------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|-----------|---|---------------|
| 23:16   | CHID          | <p>Channel ID.</p> <p>The SEC_SSTATn.CHID bits indicate the ID of the specific source (from a set of sources sharing one SEC source interface input) that asserted the SEC source interface input. An SEC source interface input may support multiple system sources, in which case the assertion must be qualified by an identifier to determine the channel that generated the assertion. The SEC_SSTATn.CHID field provides this value in the form of a numeric reference that is mapped to a specific interrupt source. The prioritization for simultaneously asserted sources is according to ID, with 0 being the highest priority. The SEC_SSTATn.CHID is captured when the SEC source interface input is acknowledged.</p> |   |           |   |               |
| 9       | ACT           | <p>Active Source.</p> <p>The SEC_SSTATn.ACT bit indicates the source has been accepted by a core for servicing, but the service is not yet complete. An SEC_SSTATn.ACT bit is set by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface. An SEC_SSTATn.ACT bit is cleared by the SEC when the core provides interrupt service end indication for the specific system interrupt through the SEC core interface.</p> <table><tr><td>0</td><td>No Source</td></tr><tr><td>1</td><td>Active Source</td></tr></table>                                                                                                                                                                | 0 | No Source | 1 | Active Source |
| 0       | No Source     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |           |   |               |

**Table 7-27:** SEC\_SSTATn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                       |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| 8       | PND      | Pending Source.<br>The SEC_SSTATn.PND bit indicates the source has signalled an interrupt request assertion, but the request has not yet been accepted by a core for servicing. A SEC_SSTATn.PND bit is set by the SEC on detection of an assertion of the corresponding system interrupt input. A SEC_SSTATn.PND bit is cleared by the SEC when the specific system interrupt is acknowledged by the core through the SEC core interface.                                                                                         |                       |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Not Pending           |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Pending               |
| 5:4     | ERRC     | Error Cause.<br>When the SEC_SSTATn.ERR bit is asserted, the SEC updates SEC_SSTATn.ERRC field to convey the interrupt source error type. When the error type is source overflow, the status indicates that a source signal assertion occurred or an SEC raise operation was attempted while pending was already set. The source overflow is detected when the source is set for edge only. When the error type is end error, the status indicates that an end was received for a source while the SEC_SSTATn.ACT bit was not set. |                       |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Source Overflow Error |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Reserved              |

## 8 Trigger Routing Unit (TRU)

The TRU provides system-level sequence control without core intervention. The TRU maps trigger masters (generators of triggers) to trigger slaves (receivers of triggers). Slave endpoints can be configured to respond to triggers in various ways. Common applications enabled by the TRU include:

- Automatically triggering the start of a DMA sequence after a sequence from another DMA channel completes
- Software triggering
- Synchronization of concurrent activities

### TRU Features

The TRU supports the following features.

- Trigger routing of any trigger master to any trigger slave.
- Software generation of any trigger master ID.
- Configuration protection through register level lock bits and global lock indication.

### TRU Functional Description

The following sections provide a function description of the TRU.

### TRU Register List

The trigger routing unit (TRU) provides simple sequence control of distributed modules without the penalties associated with core intervention (for example, interrupt overhead). The TRU resides in the SYSCCLK domain and receives trigger inputs from all master trigger inputs (MTI) and the TRU master trigger register (TRU\_MTR). Based on these inputs, the TRU logic generates trigger outputs that initiate slave operations in the processor core and peripherals. A set of registers govern TRU operations. For more information on TRU functionality, see the TRU register descriptions.

**Table 8-1:** TRU Module Registers

| Name        | Description                 |
|-------------|-----------------------------|
| TRU_SSRn    | Slave Select Register       |
| TRU_MTR     | Master Trigger Register     |
| TRU_ERRADDR | Error Address Register      |
| TRU_STAT    | Status Information Register |
| TRU_REVID   | Revision ID Register        |
| TRU_GCTL    | Global Control Register     |

## ADSP-BF60x Trigger List

## TRU Definitions

### Trigger Master

A trigger master is any system module that provides trigger event indication to the TRU. Trigger events and conditions for assertion are defined by trigger master modules.

### Trigger Master ID

Trigger masters are assigned a unique numeric ID according to their physical connection to the TRU. Trigger master ID 0 is reserved and defined as null.

### Trigger Slave

A trigger slave is any system module that receives a trigger event indication from the TRU. A trigger event response is defined by the trigger slave modules.

## TRU Block Diagram

Trigger masters and the master trigger register (MTR) generate trigger assertions. Each trigger slave has a dedicated slave select register (SSR) that specifies the unique trigger master from which it receives the trigger indication.

**Figure 8-1:** TRU Block Diagram

## TRU Architectural Concepts

The TRU supports a simple trigger-in/trigger-out model for modules that comply with the triggering functional model. The TRU is the controller of the trigger system. Trigger outputs from trigger masters are mapped to trigger inputs of trigger slaves through a set of programmable registers (SSRn). System modules may be trigger master only, trigger slave only, or trigger master and trigger slave. All of the trigger input and trigger output signals are connected to a Trigger Routing Unit (TRU) which manages the connections of triggers between modules.

## TRU Programming Model

Implementing sequence control using the TRU requires, at a minimum, proper configuration of a trigger slave, a trigger master, and the TRU module itself. The only requirement for the configuration procedure is that the trigger master should be configured and enable as the last step.

The other steps that must be completed are:

- The trigger slave must be configured for response to triggers.
- The TRU must be configured to map the trigger master to the trigger slave through the SSRn registers.
- The trigger master must be configured to generate trigger assertions.
- Alternatively, software triggering may be used for trigger assertion. Software triggers are generated by writing the trigger master ID to the MTR register.

## Programming Concepts

The following concepts will aid in programming the TRU.

- **Trigger Sequence Configuration:** A simple sequence may consist of one Trigger Master and one Trigger Slave. More complex trigger sequences may consist of several Trigger Slaves functioning as Trigger Slave AND Trigger Master. Additionally, trigger sequences may loop back to the original master forming a perpetual sequence.
- **Software Triggering:** Writing a Trigger Master ID to the MTR will generate a trigger within the TRU from the Trigger Master ID specified.
- **Synchronization:** The TRU can be used to synchronize (coarsely) events by mapping multiple Trigger Slaves to the same Trigger Master and/or by generating multiple Trigger Master assertions simultaneously through the MTR.
- **Configuration Protection:** Each SSRn and the GCTL register contain LOCK bits to enable register level write protection when Global Lock is assertion in the SPU.

## Programming Examples

The following example shows the steps to create a trigger.

### Configuring a Simple Trigger Sequence

1. Write to the GCTL register to enable the TRU
2. Write to the SSRn register of a specific trigger slave to assign it to a specific trigger master
3. Enable the trigger slave to wait for and accept a trigger
4. Enable the trigger master to generate a trigger

## TRU Event Control

The TRU is a major part of event control solutions. It is the center of the trigger functional model and may be extended to support the interrupt and fault management models as well.

## TRU Status and Error Signals

The TRU does not have dedicated status and error output signals other than the MMR interface. Slave errors are reported to the master over the standard bus protocol.

# TRU Register Descriptions

Trigger Routing Unit (TRU) contains the following registers.

Table 8-4: TRU Module Registers

| Name        | Description                 |
|-------------|-----------------------------|
| TRU_SSRn    | Slave Select Register       |
| TRU_MTR     | Master Trigger Register     |
| TRU_ERRADDR | Error Address Register      |
| TRU_STAT    | Status Information Register |
| TRU_REVID   | Revision ID Register        |
| TRU_GCTL    | Global Control Register     |

## Slave Select Register

The TRU slave select registers (TRU\_SSRn) each provide slave selection and register locking.

TRU\_SSRn: Slave Select Register - R/W

Reset = 0x0000 0000

Figure 8-2: TRU\_SSRn Register Diagram

Table 8-5: TRU\_SSRn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | SSRn Lock.<br>If the global lock is enabled (SPU_CTL_GLCK bit =1) and the TRU_SSRn . LOCK bit is enabled, the TRU_SSRn register is read only. |

**Table 8-5:** TRU\_SSRn Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | SSR      | SSRn Slave Select.<br>When a TRU_SSRn register is set (for example, TRU_SSRn is set to X), the selected slave n receives trigger X. Trigger X can be from an MTI or can be selected through software by writing X to one of the four fields in the TRU_MTR register. All TRU_MTR and MTI inputs into the TRU are rising edge sensitive. Trigger X must transition from low to high in order for a trigger to be generated. The TRU_SSRn.SSR 8-bit field of each TRU_SSRn selects an input to the trigger multiplexer, producing a TRU output. |

## Master Trigger Register

The TRU master trigger register (TRU\_MTR) permits trigger selection through software by writing X to one of the four fields in the TRU\_MTR register. Trigger inputs to the TRU can be from an MTI or the TRU\_MTR register. These inputs into the TRU are rising edge sensitive. Trigger X must transition from low to high in order for a trigger to be generated. If the global lock is enabled (SPU\_CTL\_GLCK bit =1) and the TRU\_GCTL.LOCK bit is set, the TRU\_MTR register is read only.

### TRU\_MTR: Master Trigger Register - R/W

Reset = 0x0000 0000

**Figure 8-3:** TRU\_MTR Register Diagram

**Table 8-6:** TRU\_MTR Register Fields

| Bit No. | Bit Name | Description/Enumeration    |
|---------|----------|----------------------------|
| 31:24   | MTR3     | Master Trigger Register 3. |
| 23:16   | MTR2     | Master Trigger Register 2. |
| 15:8    | MTR1     | Master Trigger Register 1. |

| Bit No. | Bit Name | Description/Enumeration    |
|---------|----------|----------------------------|
| 7:0     | MTR0     | Master Trigger Register 0. |

## Error Address Register

The TRU error address register (TRU\_ERRADDR) holds the address from the memory mapped register access generating an access error of TRU registers.

**TRU\_ERRADDR: Error Address Register - R/W**

Reset = 0x0000 0000

**Figure 8-4:** TRU\_ERRADDR Register Diagram

**Table 8-7:** TRU\_ERRADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:0    | ADDR     | <p>Error Address.</p> <p>The TRU_ERRADDR.ADDR holds the address from the memory mapped register access generating an access error of TRU registers. These errors occur on access to the TRU_SSRn or TRU_MTR registers when these registers are locked. See the TRU_SSRn and TRU_MTR register descriptions for more information about locking. The TRU_ERRADDR register holds the address of the first error to occur. In the event of both TRU_SSRn and TRU_MTR related error types occurring, the TRU_ERRADDR register contains the address of the first error. To re-enable the TRU_ERRADDR register for update, both status bits (TRU_STAT.LWERR and TRU_STAT.ADDRERR) in the TRU_STAT register must be cleared. The TRU_ERRADDR register is writeable, so the address value can be cleared using a standard MMR access.</p> |

## Status Information Register

The TRU status information register (TRU\_STAT) contains the status of TRU\_MTR and TRU\_SSRn register writes and status of bus read/write errors.

**TRU\_STAT: Status Information Register - R/W**

Reset = 0x0000 0000

**Figure 8-5:** TRU\_STAT Register Diagram

**Table 8-8:** TRU\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | ADDRERR  | Address Error Status.<br>The TRU_STAT . ADDRERR bit is set when an invalid address is provided for an MMR access while the TRU is selected. Writing a one to this bit clears the error indication. The TRU_ERRADDR register also is updated when an address error occurs during an MMR access while the TRU is selected. |
| 0       | LWERR    | Lock Write Error Status.<br>If TRU_STAT . LWERR is set, a lock write error has occurred. Writing a one to this bit clears the error indication.                                                                                                                                                                          |

## Revision ID Register

The TRU revision ID register (TRU\_REVID) is a read-only register, containing the silicon revision number.

TRU\_REVID: Revision ID Register - R/NW

Reset = 0x0000 0000

Figure 8-6: TRU\_REVID Register Diagram

Table 8-9: TRU\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:4     | MAJOR    | Major Version ID.       |
| 3:0     | REV      | Incremental Version ID. |

Global Control Register

The TRU global control register (TRU\_GCTL) provides register locking, TRU reset, and TRU enable.

TRU\_GCTL: Global Control Register - R/W

Reset = 0x0000 0000

Figure 8-7: TRU\_GCTL Register Diagram

**Table 8-10:** TRU\_GCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                          |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | GCTL Lock Bit.<br>If the global lock is enabled (SPU_CTL_GLCK bit =1) and the TRU_GCTL . LOCK bit is enabled, the TRU_GCTL register is read only.                                                                |
| 2       | MTRL     | MTR Lock Bit.<br>If the global lock is enabled (SPU_CTL_GLCK bit =1) and the TRU_GCTL . MTRL bit is enabled, the TRU_MTR register is read only.                                                                  |
| 1       | RESET    | Soft Reset.<br>The TRU_GCTL . RESET bit is write-1-action and triggers a soft reset to all TRU registers.                                                                                                        |
| 0       | EN       | Non-MMR Enable.<br>The TRU_GCTL . EN bit is read/write and must be set for the TRU to propagate trigger events. All TRU register read/write operations continue to operate independent of the TRU_GCTL . EN bit. |

## 9 Static Memory Controller (SMC)

The static memory controller is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory. It provides a glueless interface to a variety of external memories and peripheral devices, including SRAM, ROM, EPROM, NOR flash memory, and FPGA/ASIC devices.

SMC acts as an SCB slave and accesses to SMC are arbitrated by the processor SCB interconnect fabric. On the chip boundary, the SMC is connected to a 25-bit external memory address bus, a 16-bit data bus and memory control signal pins (read, write) including four chip selects via the chip pads.

### SMC Functional Description

Use the following sections to provide functional descriptions of the SMC.

- [SMC Memory Controller Definitions](#)
- [SMC Architectural Concepts](#)

### Features

SMC features include:

- 16-bit I/O width
- Supports up to 64M bytes of SRAM in each of the four external banks
- SMC supports 8-bit data masking writes
- Supports asynchronous access extension (ARDY pin)
- Allows booting from bank 0 (AMS0)
- Supports burst read with programmable burst length of 4, 8 and 16
- Provides flexible timing control through extended timing parameters

### SMC Register List

The static memory controller SMC is a protocol converter and data transfer interface between the internal processor bus and the external L3 memory. The SMC acts as a bus slave and accesses to SMC are arbitrated by the module's system crossbar. On the chip boundary, the SMC is connected to a 25 bit external memory

address bus, a 16-bit data bus and memory control signal pins (read, write) including 4 chip selects. This memory interface can support 64MB of external memory connected to 4 different banks, each bank being controlled by the chip select signal. A set of registers govern SMC operations. For more information on SMC functionality, see the SMC register descriptions.

**Table 9-1:** SMC Module Registers

| Name       | Description                     |
|------------|---------------------------------|
| SMC_GCTL   | Grant Control Register          |
| SMC_GSTAT  | Grant Status Register           |
| SMC_BOCTL  | Bank 0 Control Register         |
| SMC_B0TIM  | Bank 0 Timing Register          |
| SMC_BOETIM | Bank 0 Extended Timing Register |
| SMC_B1CTL  | Bank 1 Control Register         |
| SMC_B1TIM  | Bank 1 Timing Register          |
| SMC_B1ETIM | Bank 1 Extended Timing Register |
| SMC_B2CTL  | Bank 2 Control Register         |
| SMC_B2TIM  | Bank 2 Timing Register          |
| SMC_B2ETIM | Bank 2 Extended Timing Register |
| SMC_B3CTL  | Bank 3 Control Register         |
| SMC_B3TIM  | Bank 3 Timing Register          |
| SMC_B3ETIM | Bank 3 Extended Timing Register |

## SMC Memory Controller Definitions

The SMC contains memory-mapped registers that control the access characteristics for each asynchronous memory bank. The SMC has 1 grant control, 1 read-only grant status register and three memory control registers for each bank. All registers are 32-bit wide. Different Banks can be programmed in different Modes, independently controlled using the functional and cycle time bit settings for each bank.

The SMC\_GCTL register controls the bus grant feature of the controller. There is only one programmable bit in this register which if set disables the Bus grant feature of SMC. It is cleared at reset which means that Bus Grant is enabled by default.

The SMC\_GSTAT indicates the status of the  $\overline{BG}$ ,  $\overline{BR}$ , and  $\overline{BGH}$  pins. There are three bits in this register to reflect the status of these pins.

The SMC provides a separate set of registers SMC\_BxCTL, SMC\_BxTIM and SMC\_BxETIM to control the mode and timing characteristic of each bank independently. SMC\_BxCTL register contains bits for enabling the bank, bits for selecting mode of operation, bits to configure use of ARDY feature, bits for flash page size, synchronous burst and bits for selecting NOR clock frequency.

SMC\_BxCTL also contains bits to control the type of bank select control signal. External FIFO devices often do not have a separate chip select pin. As a result, for a read, the FIFO's output enable ( $\overline{OE}$ ) pin must be connected to the OR (negative AND) of the  $\overline{AMS}$  and the  $\overline{ARE}$ . Similarly, the write case requires an OR between  $\overline{AMS}$  and  $\overline{AWE}$ . The SMC provides this function so that an external OR gate is not required. The appropriate AMS function can be selected for each memory bank region using the BxSELCTRL bits in SMC\_BxCTL register.

SMC\_BxTIM register contains bits to program the setup time, hold time and access time for read and write access to each bank separately. SMC now allows for totally different setup/hold/access times for Reads and Writes. SMC\_BxTIM register allows to control the timing characteristics of the asynchronous memory interface using following parameters.

- Read Setup time – The time between the beginning of a memory cycle ( $\overline{AMSx}$  low) and the read-enable assertion ( $\overline{ARE}$  low).
- Read Hold time – The time between read-enable deassertion ( $\overline{ARE}$  high) and the end of the memory cycle ( $\overline{AMSx}$  high).
- Read Access – The time between read-enable assertion ( $\overline{ARE}$  low) and deassertion ( $\overline{ARE}$  high).
- Write Setup time – The time between the beginning of a memory cycle ( $\overline{AMSx}$  low) and the write-enable assertion ( $\overline{AWE}$  low).
- Write Hold time – The time between write-enable deassertion ( $\overline{AWE}$  high) and the end of the memory cycle ( $\overline{AMSx}$  high).
- Write Access – The time between write-enable assertion ( $\overline{AWE}$  low) and deassertion ( $\overline{AWE}$  high).

Each of these parameters can be programmed in terms of SCLK0 clock cycles.

SMC provides another register for defining additional timing characteristics of control signals by programming the extended timing register SMC\_BxETIM. The SMC\_BxETIM register provides bits to program following timing characteristics.

- Pre-Setup time – The number of cycles  $\overline{AMS}$  is asserted before  $\overline{AOE}$  is asserted.
- Pre-Access time – The number of cycles inserted after  $\overline{ADV}$  is de-asserted, before  $\overline{ARE}$  is asserted for the next access.

- Memory Idle time – The number of bus idle cycles between  $\overline{\text{AMS}}$  de-asserting edge and next asserting edge.
- Memory Transition time – The number of bus idle cycles extending the Idle time cycles in case of the subsequent access has a different data direction or is to different bank.

## SMC Architectural Concepts

Like earlier Blackfin processors the ADSP-BF60x does not directly support 8-bit accesses to the external memories so for this reason the A0 pin has not been provided out of the processor. Hence address lines coming out of the chip are from A1 to A25. But 8-bit accesses are indirectly supported through additional byte enable signals ABE[1:0]. Some 16 bit memory systems allow the Blackfin processor to do 8-bit reads and writes. The byte to be read or written is selected through the ABE0 and ABE1 signals.

The ABE[1:0] pins are both low during all asynchronous reads and 16-bit asynchronous writes. When an asynchronous write is made to the upper byte of a 16-bit memory, ABE1 = 0 and ABE0 = 1. When an asynchronous write is made to the lower byte of a 16-bit memory, ABE1 = 1 and ABE0 = 0.

The SMC can support 64 MB of external memory connected to four different banks—each bank is controlled by the chip select signal. Accesses to the address range of a particular bank cause the chip select of that bank to get asserted.

Table1. Asynchronous Memory Bank Address Range

| Memory Bank Select         | Memory Bank          | Address Start | Address End |
|----------------------------|----------------------|---------------|-------------|
| $\overline{\text{AMS}}[3]$ | Static Memory Bank-3 | 0xBC00 0000   | 0xBFFF FFFF |
| $\overline{\text{AMS}}[2]$ | Static Memory Bank-2 | 0xB800 0000   | 0xBBFF FFFF |
| $\overline{\text{AMS}}[1]$ | Static Memory Bank-1 | 0xB400 0000   | 0xB7FF FFFF |
| $\overline{\text{AMS}}[0]$ | Static Memory Bank-0 | 0xB000 0000   | 0xB3FF FFFF |

Address range allocated to each bank is fixed at 64MByte. However, not all of an enabled memory bank need be populated.

## Avoiding Bus Contention

When using the three-stateable data bus in a system with multiple devices, use care to avoid bus contention. Contention causes excessive power dissipation and can lead to device failure. Contention occurs during the time one device is getting off the bus and another is getting on. If the first device is slow to three-state and the second device is quick to drive, the devices contend. There are two cases where contention can occur. The first case is a read followed by a write to the same memory space. In this case, the data bus drivers can potentially contend with those of the memory device addressed by the read. The second

case is back-to-back reads from two different memory spaces. In this case, the two memory devices addressed by the two reads could potentially contend at the transition between the two read operations.

To avoid contention, program the turnaround time appropriately in the `SMC_BxETIM` registers. This feature allows software to set the number of clock cycles between these types of accesses on a bank-by-bank basis.

Idle time (`BxIT`) applies to similar back to back access types on the same bank. For actual turnaround scenarios idle time and transition time (`BxTT`) function in an accumulated fashion. The sequence of access types and the field(s) that affect access times are shown below.

- a write followed by write to same bank - `B0IT`
- a read followed by read to same bank - `B0IT`
- a write followed by read to same bank - `B0IT + B0TT`
- a read followed by write to same bank - `B0IT + B0TT`
- any access to a given bank followed by any access to a different bank - `B0IT + B0TT`

The reset value of turnaround transition time is 2 cycles. It is recommended that `BxTT` be programmed to a value either greater than or equal to 2 cycles depending upon memory AC-timing specifications. However, `BxTT` may be programmed to 0 ONLY if:

1. No SMC Bank is programmed in synchronous burst mode AND
2. There are either only read accesses or only write accesses possible to external memory devices for the current device configuration/processor operation scenario.

## ARDY Input Control

Each bank can be programmed to sample the ARDY input after the read or write access timer has counted down or to ignore this input signal. If enabled and disabled at the sample window, ARDY can be used to extend the access time as required.

The ARDY input is treated as an asynchronous input, however it must reach the desired value (either asserted or deasserted) more than two SCLK0 cycle before the completion of access time (scheduled rising edge of  $\overline{AWE}$  or  $\overline{ARE}$ ). This determines whether the access is extended or not, the transaction is extended by the assertion of ARDY. Once ARDY (asserted by memory device), is sampled 'HIGH' the total delay between ARDY going high at the pads and  $\overline{ARE}$  being de-asserted at the pads can be a maximum of 5 SCLK cycles.

Asynchronous SRAM writes are also possible with ARDY signal enabled. In Asynchronous SRAM writes with ARDY, the Write Access is extended beyond programmed write access cycles depending on the ARDY signal state. Once ARDY is sampled ASSERTED, the  $\overline{AWE}$  signal is deasserted after 2 CLKOUT cycles and the write access ends.

The polarity of ARDY is programmable on a per-bank basis. Since ARDY is not sampled until an access is in progress to a bank in which the ARDY enable is asserted, ARDY does not need to be driven by default. When

using flash memory, the WAIT input should be connected to ARDY. To avoid stalls in case of erroneous ARDY behavior, the ARDYABRTEN bit can be set to enable the ARDY Abort Counter. If ARDY abort counter is enabled, then the counter starts counting down as soon as the programmed read/write access cycles expire, and times out generating an error if ARDY is not sampled asserted within 64 cycles. This ensures that processor/test does not hang in case ARDY is not sampled correctly.

## Bus Request and Bus Grant

The SMC can relinquish control of the data and address buses to an external device, using the bus request and bus grant protocol. SMC three states its memory interface to allow an external controller to access either external asynchronous or synchronous memory parts.

When an external controller requires access to the static memory bus, it asserts the bus request ( $\overline{BR}$ ) signal. If no internal SMC request is pending, and if the SMC is in the IDLE state, the SMC grants the external bus request. A bus grant is initiated by the following.

- Three-stating the data and address buses and the memory control signals.
- Asserting the bus grant ( $\overline{BG}$ ) signal.

When the static memory bus is granted to an external controller, the SMC stalls all accesses, including instruction fetches and data reads/writes, that address the SMC memory space. Bus grant status may be checked through examination of the `SMC_GSTAT.BGSTAT` bit. This bit can be used by software to check the bus grant status prior to initiating transactions that would be delayed by the external bus grant. When the SMC is ready to perform an access, but is held off because the bus is granted, it asserts the bus grant hang ( $\overline{BGH}$ ) pin. When the external controller releases ( $\overline{BR}$ ), the SMC de-asserts ( $\overline{BG}$ ) and continues servicing access requests.

## Bank-Off Bus Grant

The SMC bus is granted during system reset and after system reset before any one of the SMC banks is enabled. Since all SMC banks are disabled at reset, including bank 0, the SMC bus is granted by default. This bank-off bus grant state does not depend on the status of the external bus request signal. During this bank-off bus grant state, the  $\overline{BG}$  signal is asserted low and the  $\overline{BGH}$  signal is unchanged since internal requests are not possible when all SMC banks are disabled. The state of `SMC_GCTL.BGDIS` bit has no effect during the bank-off bus grant state.

When an SMC bank is enabled, it transitions from the bank-off bus grant state to the active state, during which bus grant depends on external bus request ( $\overline{BR}$ ), on internal access requests, and on SMC settings (for example the `SMC_GCTL.BGDIS` bit). If after SMC operation all SMC banks are disabled, the SMC transitions to the bank-off bus grant state, during which the SMC bus is granted irrespective of external bus request status.

## Bus Request and Bus Grant Protocol Timing

Fig. shows the bus cycles for the bus request and bus grant protocol. The external device bus request signal ( $\overline{BR}$ ) is latched on the rising edge of  $SCLK$ . If the SMC is in the idle state (no access requests pending), the bus grant ( $\overline{BG}$ ) signal is asserted 3.5 cycles later on the falling edge of  $CLKOUT$ . The SMC transitions to the bus grant state, three-stating all SMC buses ( $ADDR$ ,  $DATA$ ,  $\overline{AMS}$ ).

If an internal access request is issued while the SMC has the bus granted, the bus grant hang ( $\overline{BGH}$ ) signal is asserted 1.5 cycles later on the falling edge of  $CLKOUT$ .

When the ( $\overline{BR}$ ) signal is de-asserted by the external memory controller, signaling that the external device is relinquishing control of the bus, the SMC latches the state of ( $\overline{BR}$ ) on the rising edge of  $SCLK$ , and 3.5 cycles later, de-asserts ( $\overline{BG}$ ) and ( $\overline{BGH}$ ) on the falling edge of  $CLKOUT$ , transitions from the bus grant state into the active state and resumes processing pending access requests.

**NOTE: IMPORTANT:** When asserting  $\overline{BR}$  low the external host must wait for 3.5 more  $SYSCLK$  cycles before sampling  $\overline{BG}$ , where a single  $\overline{BG}$  sample is used to initiate multi-cycle bus use.

Figure 9-1: SMC Bus Request Bus Grant Protocol

## Disabling Bus Grant to External Memory Controllers

By default, the bus grant feature of the SMC is enabled. To configure the SMC to ignore bus requests and the status of the  $\overline{BR}$  pin, set the  $SMC\_GCTL.BGDIS$  bit.

If the  $SMC\_GCTL.BGDIS$  bit is set while the bus is granted to an external memory controller, the current bus grant status is not affected. The bus continues to be granted until the external memory controller relinquishes control of the bus. At that point, subsequent bus requests are ignored.

## SMC Operating Modes

The SMC supports the following memory devices and operating modes.

- Asynchronous SRAMs
- Flash memories in asynchronous access mode
- Flash memories in synchronous burst mode
- Flash memories in asynchronous page mode
- Asynchronous FIFO devices

### Asynchronous Flash Mode

When the access selected mode is asynchronous flash (MODE = 01), external bank accesses operate exactly the same as in standard asynchronous mode, except for the pin configuration. This mode should be used when accessing burst devices in non-read array modes.

### Synchronous Burst Mode

When synchronous mode access is selected (MODE = 11), synchronous reads are enabled. The burst clock frequency can be configured for SCLK0, SCLK0/2, SCLK0/3 or SCLK0/4. This is the frequency of the clock output and determines the frequency of latching data for subsequent beats of a burst. It does not affect any of the other timing parameters (which are still determined by SMC\_BxTIM and SMC\_BxETIM). During the setup time of an access,  $\overline{ADV}$  is asserted and the burst clock begins running.  $\overline{ADV}$  is asserted for the entire setup time. First rising edge of burst clock (NOR\_CLK) coincides with fall of CLKOUT at the assertion of  $\overline{ADV}$ .

Once the address is latched, the initial burst access occurs based on the read access timing for that bank. The strobe time is then extended by a burst clock duration for each subsequent beat of the burst. Any access in the burst may be extended by connecting the flash WAIT to ARDY. The flash device must be configured to deassert ARDY at the same time that data is valid. There are cases when the NOR\_WAIT is asserted by the flash device in the middle of a read burst (for page crosses). In such cases, Read data latching STOPS until NOR\_WAIT is again deasserted by the flash device, after which data is latched on every rising edge of NOR\_CLK.

The synchronous read may be burst or single mode, depending on the type of transfer requested. Burst access is only supported for back-to-back reads, such as cache line fills (16 words), 64-bit instruction reads (4 words), and DMA reads. Write accesses in synchronous flash burst mode go through as simple asynchronous flash writes. This allows easy programming and re-programming of flash configuration registers while the bank is programmed in synchronous burst mode.

## Asynchronous Page Mode

When asynchronous page mode access is selected (MODE = 10), asynchronous page reads are enabled. Page sizes of 4, 8 and 16 words are supported. When performing a page mode read, the first access in the page proceeds according to the read access time configured in SMC\_BxTIM register. This opens the page, the subsequent reads in that page have a period equal to the page wait states programmed in SMC\_BxETIM register. Besides the start of the setup phase, the read address is incremented at the start of every page cycle.

Page mode access is only supported for back-to-back accesses, such as cache line fills (16 words), 64-bit instruction reads (4 words) and DMA reads. Write accesses in asynchronous page mode are treated as simple asynchronous flash write accesses.

## SMC Event Control

The information for this section is TBD.

## SMC Errors

Accesses to reserved locations and writes to read only registers will result in bus Errors. Bus errors are translated into internal SCB Crossbar errors which in turn get translated into interrupt. To report errors occurring in the slave memory devices (for both this memory interface and the MMR interface as well), the core combines the SCB Crossbar response signals to generate a combined error signal indication which is routed to the fault management unit.

## SMC Programmable Timing Characteristics

This section describes the programmable timing characteristics for the SMC. Timing relationships depend on the programming of the SMC bank registers, whether initiation is from the core or from DMA, and the sequence of transactions (read followed by read, read followed by write, and others).

Note: All memory control, address and data signals are driven out of chip with regard to the falling edge of CLKOUT, except for burst clock. CLKOUT is SCLK0 on the chip pins (pad delayed).

## Asynchronous SRAM Reads and Writes

The figure below shows a basic single write and read operation to an external device with SMC programmed in asynchronous SRAM mode. For the current bank, the programmed time cycles are:

- write setup time = 2 cycles
- write access time = 4 cycles
- write hold time is = 2 cycles

- read setup time = 3 cycles
- read access time = 5 cycles
- read hold time = 1 cycle
- turnaround transition time = 2 cycles
- idle transition time = 0 cycles

The asynchronous SRAM bus cycles proceed as follows.

- At the start of the write setup period, the  $\overline{\text{AMS}}$  signal for the target bank asserts. The write data  $\text{WD0}$ , address  $\text{AW0}$  and byte enables become valid.
- At the end of the setup phase and at the start of the write access period, the write enable  $\overline{\text{AWE}}$  asserts.
- At the end of the programmed write access, the  $\overline{\text{AWE}}$  de-asserts. The target device is assumed to have captured the write data before  $\overline{\text{AWE}}$  de-asserts.
- At the end of the write hold period,  $\overline{\text{AMS}}$  de-asserts since the pending access is a read access, and the turnaround transition time cycles start. The write data and byte enables become invalid within 1 cycle of  $\overline{\text{AMS}}$  de-asserting.
- At the end of turnaround transition time, the read setup period starts with  $\overline{\text{AMS}}$  and  $\overline{\text{AOE}}$  being asserted and a new read address  $\text{AR0}$  being presented on the Address Bus.
- At the start of the read access period, the read enable signal  $\overline{\text{ARE}}$  asserts.
- At the end of the read access period, the  $\overline{\text{ARE}}$  signal de-asserts and the read hold period starts. Read data is latched along with  $\overline{\text{ARE}}$  de-asserting.
- At the end of the read hold period, the chip select  $\overline{\text{AMS}}$  is pulled high and turnaround transition cycles are appended unless there is a pending read request to the same bank.

**Figure 9-2:** Basic Asynchronous SRAM Write Followed by Read

## Asynchronous SRAM Reads with IDLE Transition Cycles Inserted

The following figure shows two consecutive asynchronous SRAM mode reads to the same bank separated by programmed IDLE transition time cycles. Programmed cycle times are:

- RST= 2 cycles
- RAT= 4 cycles
- RHT= 1 Cycle
- IDLE trans. time = 2 Cycles

At the start of the IDLE Transition cycle,  $\overline{AMS}$  and  $\overline{AOE}$  are de-asserted. The setup period of the second read starts at the end of the IDLE transition cycle with the assertion of  $\overline{AMS}$  and  $\overline{AOE}$ , and new address on the address bus.

**Figure 9-3:** Asynchronous SRAM Read with IDLE Transition

## High Speed Asynchronous SRAM Read Burst

The following figure shows a high speed asynchronous SRAM read bus cycle. This is typical for SRAM devices with small access times being accessed through SCB read bursts, especially for boot purposes. In this case, the target SMC bank has been programmed with:

- read setup time = 1 cycle
- read access time = 2 cycles
- read hold time = 0
- PREAT= 0
- PREST= 0
- IDLE transition time = 0

The  $\overline{AMS}$  signal asserts at the start of the setup cycle of the first read out of the burst. Since hold time and IDLE transition time have been programmed to 0,  $\overline{AMS}$  does not de-assert until the entire set of reads is over. Only the  $\overline{ARE}$  signal de-asserts periodically for 1 cycle for the setup period. Read address changes to the next address at the start of each individual setup cycle. Read data words are latched at the end of each individual read access period.

**Figure 9-4:** Fast Asynchronous SRAM Reads, Burst of Four Word

## High Speed Asynchronous SRAM Writes

High speed asynchronous SRAM writes are similar to the high speed read accesses. The bus protocol is shown in the following figure for a write burst of 4 words. Here, write setup time is 1 cycle and write access time has been programmed to 2 cycles. Write hold time, pre access time, pre-setup time and idle transition time have programmed to 0. The chip select signal  $\overline{AMS_n}$  asserts at the start of the entire write burst and de-asserts only at the end of the last individual write access period. Write Address, byte enables and write data for each individual write access are presented onto the bus at the start of each individual write setup cycle. The  $\overline{AWE}$  signal asserts for the write access period and de-asserts during the setup period for each individual data write.

**Figure 9-5:** Fast Asynchronous SRAM Writes

## Asynchronous SRAM Read with ARDY

The following figure shows an extended asynchronous SRAM read bus cycle with ARDY enabled. The programmed SMC bank control parameters are:

- Pre-Setup Time = 1 cycle
- Read Setup Time = 3 Cycles
- Read Access Time = 6 Cycles
- Read Hold Time = 2 Cycles,
- ARDYPOL = 1 (memory is ready when ARDY = 1)

The bus cycles proceed as follows:

- At the start of the pre-setup phase,  $\overline{AMS}$  asserts, and read address A0 is presented on the ADDR bus.
- At the start of the setup period,  $\overline{AOE}$  asserts.
- At the start of the read access,  $\overline{ARE}$  asserts.

- CLKOUT is SCLK which is driven out of the pads. CLKOUT falling edge can be delayed from the internal SCLK fall edge up to 1.5 SCLK cycles for SCLK=125 MHz. All output signals out of the pads for example  $\overline{ARE}$  and  $\overline{AOE}$  are driven with regard to the falling edge of CLKOUT.
- 2 cycles before the programmed number of read access cycles expires, SMC starts sampling ARDY on every rising edge of internal SCLK. Read access is extended ( $\overline{ARE}$  is kept asserted) until ARDY is sampled HIGH.
- Once ARDY (asserted by memory device), is sampled HIGH in SCLK, the read signal is pulled off internally in SCLK domain. The total delay between ARDY going high at the pads and  $\overline{ARE}$  being de-asserted at the pads can be a maximum of 5 SCLK cycles.
- Read data is latched at the falling edge of CLKOUT on the same edge where  $\overline{ARE}$  is deasserted.
- Hold bus cycles start after the  $\overline{ARE}$  is de-asserted.
- At the end of the hold period,  $\overline{AMS}$  and  $\overline{AOE}$  de-assert and the SMC goes into transition state.

Figure 9-6: Asynchronous SRAM Read with ARDY

## Asynchronous Flash Read Operation

The following figure illustrates a single asynchronous flash mode read bus cycle. In this case, the target SMC bank has been programmed with:

- pre-setup time = 1 cycle
- read setup time = 2 cycles
- pre-access time = 1 cycle
- read access time = 5 cycles
- read hold time = 2 cycles.

The read bus cycle is almost identical to the asynchronous SRAM read bus cycle. The only difference is the behavior of  $\overline{AOE}$  signal which is used as the flash address valid  $\overline{NOR\_ADV}$ .  $\overline{NOR\_ADV}$  asserts at the start of the setup cycle and de-asserts at the end of the setup cycle.

The pre-access cycle inserts 1 cycle gap between the de-assertion of  $\overline{NOR\_ADV}$  and the assertion of Flash Read strobe  $\overline{NOR\_OE}$  at the start of read access. asynchronous flash reads can also be used with  $\overline{ARDY}$  enabled for flash devices which use  $\overline{NOR\_WAIT}$  in asynchronous mode. In that case, the read bus cycle operation is identical to the asynchronous SRAM with  $\overline{ARDY}$  enabled except for the  $\overline{AOE}$  ( $\overline{NOR\_ADV}$ ) signal behavior.

**Figure 9-7:** Asynchronous Flash Read with Pre-Setup and Pre-Access Cycles

The following figure shows a 32-bit read access to a flash device in asynchronous mode. A 32-bit read access to SMC is split into two 16-bit external memory accesses as shown in the figure. For this bank, read setup and read hold are programmed as 2 cycles whereas the read access time is 5 cycles. Note that the flash device chip select  $\overline{NOR\_CE}$  remains asserted for the entire duration of both read accesses, and is de-asserted at the end of the hold period of the second read access.  $\overline{NOR\_ADV}$  is asserted during the setup phase of both read accesses. Read data is latched at the end of the read access period.

**Figure 9-8:** 32-bit Asynchronous Flash Read

## Asynchronous Flash Write Operation

The following figure shows a single asynchronous flash write bus cycle. For this example, the SMC has been programmed with:

- pre-setup time = 1 cycle
- write setup time = 2 cycles
- write access time = 6 cycles
- write hold time = 2 cycles
- pre-access time = 0

The asynchronous flash write bus cycle is again almost identical to the asynchronous SRAM write. The  $\overline{AWE}$  pin is connected to flash write enable  $\overline{NOR\_WE}$ . However, in asynchronous flash writes, the  $\overline{AOE}$  signal is used as the address valid  $\overline{NOR\_ADV}$  and asserts for the duration of the setup period, unlike in asynchronous SRAM writes where  $\overline{AOE}$  never asserts.

**Figure 9-9:** Asynchronous Flash Write Operation

## Asynchronous Flash Page Mode Read operation

The following figure shows an asynchronous page mode bus read cycle for a burst of 5 reads which are split into 4 reads followed by a single read. The programmed bank parameters are:

- read setup time = 2 cycles
- read access time = 6 cycles
- page wait = 2 cycles
- hold time = 2 cycles

The maximum number of read bursts in a total page access depends on the bank PGSZ bits (00: 4 words, 01: 8 words, 1x: 16 words) The first read access is extended for 3 more page-read cycles whose period is equal to the page wait states. Besides the start of the setup phase, the read address is incremented at the start of every page cycle. Read data is latched with the falling edge of CLKOUT the end of the read access period, and also at the end of the page cycles.

**Figure 9-10:** Asynchronous Page Mode Read Bus Cycle

## Synchronous Burst Mode Read Operation

The following figure shows a synchronous burst mode read operation for a 4 word burst. The Xlatency in the flash device has been programmed to 3, and the burst clock division value is 2. Therefore, the computed read cycle parameters are:

- read setup time = 2 cycles
- read access time = 5 cycles
- read hold time = 1 cycle

The SMC Bus cycles proceed as follows:

- At the start of the read setup period,  $\overline{\text{NOR\_CE}}$  and  $\overline{\text{NOR\_ADV}}$  assert. Read address is presented on the NOR\_A bus. First rising edge of burst clock (NOR\_CLK) coincides with fall of CLKOUT at this edge.
- At the end of the read setup period, which is exactly 1 NOR\_CLK wide,  $\overline{\text{NOR\_ADV}}$  deasserts, and read access starts with  $\overline{\text{NOR\_OE}}$  being asserted.
- Flash de-asserts NOR\_WAIT signal after 2 NOR\_CLK cycles after  $\overline{\text{NOR\_OE}}$  is asserted, as Xlatency has been fixed at 3. (Here, NOR\_WAIT is programmed as active low in flash)

- Read access period ends after 5 CLKOUT cycles, after which NOR\_WAIT is sampled at every rising edge of NOR\_CLK.
- After NOR\_WAIT has been sampled high, read data words are latched on subsequent rising edges of NOR\_CLK, and the read access is extended for 10 CLKOUT cycles, after which the SMC deasserts  $\overline{\text{NOR\_OE}}$  terminating the 4 word burst.
- At the end of the hold period,  $\overline{\text{NOR\_CE}}$  de-asserts, and transition cycles start.
- NOR\_CLK toggle stops with the end of the read access. The last rising edge of NOR\_CLK occurs before  $\overline{\text{NOR\_OE}}$  rises.

**Figure 9-11:** Synchronous Burst Mode Read Operation, Burst of 4 Words, DIV = 2, XLAT = 3

## Asynchronous FIFO Read and Write Operation

The following figure shows read bus cycles for an asynchronous FIFO device. The SMC bank has been programmed in asynchronous SRAM mode, with  $\text{SELCTRL} = 01$  ( $\overline{\text{AMS}}$  is OR-ed with  $\overline{\text{ARE}}$ ). Other settings are:

- read setup time = 1 cycle
- read access time = 3 cycles
- read hold time = 1 cycle

- idle transition time = 0 cycles
- turnaround transition time = 2 cycles

The  $\overline{AMS}$  signal is connected to the read enable (RE) of the FIFO device, and DATA bus is connected to the output data bus (DQ) of the FIFO.  $\overline{AMS}$  or the FIFO read strobe asserts only for the duration of the read access. Read data is latched at the falling edge of CLKOUT at the end of the read access, when  $\overline{AMS}$  is deasserted.

**Figure 9-12:** Asynchronous FIFO Read Bus Cycles

The following figure illustrates write bus cycles for an asynchronous FIFO device. The SMC bank has been programmed in asynchronous SRAM mode, with  $SELCTRL = 10$  ( $\overline{AMS}$  is OR-ed with  $\overline{AW\overline{E}}$ ). Other settings are:

- write setup time = 1 cycle
- write access time = 3 cycles
- write hold time = 1 cycle
- idle transition time = 0
- turnaround transition time = 2 cycles

The  $\overline{AMS}$  signal is connected to the write enable ( $\overline{WE}$ ) of the FIFO device, and DATA bus is connected to the input data bus (DIN) of the FIFO. The  $\overline{AMS}$  signal or the FIFO write strobe asserts only for the duration of the write access. However, write data is asserted at the start of the setup cycle and is taken off at the end of the hold period for each individual write access.

**Figure 9-13:** Asynchronous FIFO Write Bus Cycles

## SMC Programming Model

Following are general guidelines for configuring and enabling the SMC interface. Failure to follow these guidelines can lead to erroneous behavior.

- In asynchronous page mode, the `ARDYEN` bit should always be 0.
- The `ARDY` abort counter should be enabled (the `ARDYBRTEN` bit = 1) whenever `ARDY` is enabled (`ARDYEN` is set to 1). Doing so ensures that the interface does not hang due to erroneous `ARDY` behavior or erroneous sampling of the `ARDY` signal.
- Read access time (`RAT`), write access time (`WAT`), read setup time (`RST`), and write setup time (`WST`) should not be programmed to zero.
- Page mode wait states (`PGWS`) should never be programmed to 0 or 1.
- Program the burst type (`BTYPE`) and the page size bits (`PGSZ`) in the `SMC_BxCTLK` register to match the configurations of the flash device that is being connected to the SMC interface.
- The `RDYPOL` bit should be selected to be the complement of the `WAIT` polarity that is configured in the flash device.
- In asynchronous SRAM and asynchronous flash modes with `ARDY` enabled and where `RHT`, `WHT`, `RAT`, `WAT` are the read and write hold and access times and `IT` and `TT` are the idle and transition times ensure that:
  - $RHT + IT + TT \geq 2$
  - $WHT + IT + TT \geq 2$
  - $RAT \geq 5$
  - $WAT \geq 5$

In synchronous burst mode, program:

- $RST = m \times (BCLKDIV + 1)$ ; where BCLKDIV is the value programmed in the BCLK bit field in SMC\_BxCTL, and  $m = 1, 2, 3, \dots$
- $PREAT = n \times (BCLKDIV + 1)$ ; where BCLKDIV is the value programmed in the BCLK bit field in SMC\_BxCTL, and  $n = 0, 1, 2, \dots$
- $RAT = XLAT \times (BCLKDIV + 1) + 1 - PREAT - RST$ ; where XLAT is the X latency value programmed in the synchronous burst flash device.
- $RHT = BCLKDIV$

Also in synchronous burst mode ensure that:

- $IT + TT \geq 2$
- ARDYEN should always be 1

## SMC Register Descriptions

Static Memory Controller (SMC) contains the following registers.

**Table 9-2:** SMC Module Registers

| Name       | Description                     |
|------------|---------------------------------|
| SMC_GCTL   | Grant Control Register          |
| SMC_GSTAT  | Grant Status Register           |
| SMC_BOCTL  | Bank 0 Control Register         |
| SMC_B0TIM  | Bank 0 Timing Register          |
| SMC_BOETIM | Bank 0 Extended Timing Register |
| SMC_B1CTL  | Bank 1 Control Register         |
| SMC_B1TIM  | Bank 1 Timing Register          |
| SMC_B1ETIM | Bank 1 Extended Timing Register |
| SMC_B2CTL  | Bank 2 Control Register         |
| SMC_B2TIM  | Bank 2 Timing Register          |
| SMC_B2ETIM | Bank 2 Extended Timing Register |

Table 9-2: SMC Module Registers (Continued)

| Name       | Description                     |
|------------|---------------------------------|
| SMC_B3CTL  | Bank 3 Control Register         |
| SMC_B3TIM  | Bank 3 Timing Register          |
| SMC_B3ETIM | Bank 3 Extended Timing Register |

Grant Control Register

The SMC\_GCTL register controls SMC's bus request operation.

SMC\_GCTL: Grant Control Register - R/W

Reset = 0x0000 0000

Figure 9-14: SMC\_GCTL Register Diagram

Table 9-3: SMC\_GCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | BGDIS    | Bus Grant Disable.<br>The SMC_GCTL.BGDIS bit disables the SMC's bus request feature, disabling operation of the $\overline{\text{SMC\_BG}}$ , $\overline{\text{SMC\_BR}}$ , and $\overline{\text{SMC\_BGH}}$ pins. |
|         |          | 0                      Enable                                                                                                                                                                                      |
|         |          | 1                      Disable                                                                                                                                                                                     |

Grant Status Register

The SMC\_GSTAT register indicates the status of the  $\overline{\text{SMC\_BG}}$ ,  $\overline{\text{SMC\_BR}}$ , and  $\overline{\text{SMC\_BGH}}$  pins.

**SMC\_GSTAT: Grant Status Register - R/NW**

Reset = 0x0000 0001

**Figure 9-15:** SMC\_GSTAT Register Diagram

|         |          | 1 Burst clock = SCLK / 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 2 Burst clock = SCLK / 3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 3 Burst clock = SCLK / 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 21:20   | PGSZ     | Flash Page Size.<br>The SMC_BOCTL.PGSZ bits select the flash page size, if page flash or sync burst flash protocol has been enabled (SMC_BOCTL.MODE > 1). Note that the SMC_BOCTL.PGSZ bits must be set to match the flash protocol of the external flash memory device in the system. The typical SMC_BOCTL.PGSZ selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical SMC_BOCTL.PGSZ selection for external devices supporting sync burst flash protocol is 16 words. |

| 14      | RDYABTEN | ARDY Abort Enable.<br>The SMC_BOCTL.RDYABTEN bit enables the abort counter for the SMC_ARDY pin, if enabled (SMC_BOCTL.RDYEN = 1). After SMC_BOTIM.RAT or SMC_BOTIM.WAT cycles, the SMC starts sampling the SMC_ARDY pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK. If the SMC detects that SMC_ARDY remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus.                                                      |
|         |          | 0 Disable abort counter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1 Enable abort counter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 9-5:** SMC\_BOCTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                            |                     |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| 13      | RDYPOL   | ARDY Polarity.<br>The SMC_BOCTL.RDYPOL bit selects the polarity (active high or low) for the SMC_ARDY pin, if enabled (SMC_BOCTL.RDYEN =1). When the SMC samples the SMC_ARDY pin in the selective active state, the transaction completes.                                                        |                     |
|         |          | 0                                                                                                                                                                                                                                                                                                  | Low active ARDY     |
|         |          | 1                                                                                                                                                                                                                                                                                                  | High active ARDY    |
| 12      | RDYEN    | ARDY Enable.<br>The SMC_BOCTL.RDYEN bit enables SMC_ARDY pin operation for bank 0 accesses. When enabled, the SMC uses SMC_ARDY (after the access time countdown) to determine completion of access to this memory bank. When disabled, the SMC ignores SMC_ARDY for accesses to this memory bank. |                     |
|         |          | 0                                                                                                                                                                                                                                                                                                  | Disable ARDY        |

## Bank 0 Timing Register

The SMC\_B0TIM register configures bank 0 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

**SMC\_B0TIM: Bank 0 Timing Register - R/W**

Reset = 0x0101 0101

Bank 0 Extended Timing Register

The SMC\_B0ETIM register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the SMC\_B0TIM register.

SMC\_B0ETIM: Bank 0 Extended Timing Register - R/W

Reset = 0x0002 0200

**Table 9-8:** SMC\_B1CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                       |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| 14      | RDYABTEN | ARDY Abort Enable.<br>The SMC_B1CTL.RDYABTEN bit enables the abort counter for the SMC_ARDY pin, if enabled (SMC_B1CTL.RDYEN =1). After SMC_B1TIM.RAT or SMC_B1TIM.WAT cycles, the SMC starts sampling the SMC_ARDY pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK. If the SMC detects that SMC_ARDY remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus. |                       |

## Bank 1 Timing Register

The SMC\_B1TIM register configures bank 1 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

**SMC\_B1TIM: Bank 1 Timing Register - R/W**

Bank 1 Extended Timing Register

The SMC\_B1ETIM register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the SMC\_B1TIM register.

Bank 2 Control Register

The SMC\_B2CTL register enables bank 2 accesses and configures the memory access features for this bank.

SMC\_B2CTL: Bank 2 Control Register - R/W

Reset = 0x0100 0000

| 21:20   | PGSZ     | Flash Page Size.<br>The SMC_B2CTL.PGSZ bits select the flash page size, if page flash or sync burst flash protocol has been enabled (SMC_B2CTL.MODE > 1). Note that the SMC_B2CTL.PGSZ bits must be set to match the flash protocol of the external flash memory device in the system. The typical SMC_B2CTL.PGSZ selection for external devices supporting async flash or async flash page protocols is 4 or 8 words. The typical SMC_B2CTL.PGSZ selection for external devices supporting sync burst flash protocol is 16 words. |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                       |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| 14      | RDYABTEN | ARDY Abort Enable.<br>The SMC_B2CTL.RDYABTEN bit enables the abort counter for the SMC_ARDY pin, if enabled (SMC_B2CTL.RDYEN =1). After SMC_B2TIM.RAT or SMC_B2TIM.WAT cycles, the SMC starts sampling the SMC_ARDY pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK. If the SMC detects that SMC_ARDY remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus. |                       |

## Bank 2 Timing Register

The SMC\_B2TIM register configures bank 2 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

**SMC\_B2TIM: Bank 2 Timing Register - R/W**

Bank 2 Extended Timing Register

The SMC\_B2ETIM register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the SMC\_B2TIM register.

Bank 3 Control Register

The SMC\_B3CTL register enables bank 3 accesses and configures the memory access features for this bank.

SMC\_B3CTL: Bank 3 Control Register - R/W

Reset = 0x0100 0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                       |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| 14      | RDYABTEN | ARDY Abort Enable.<br>The SMC_B3CTL.RDYABTEN bit enables the abort counter for the SMC_ARDY pin, if enabled (SMC_B3CTL.RDYEN =1). After SMC_B3TIM.RAT or SMC_B3TIM.WAT cycles, the SMC starts sampling the SMC_ARDY pin and starts the abort down counter (if enabled). The abort count is 64 cycles of SCLK. If the SMC detects that SMC_ARDY remains de-asserted when the counter expires, the SMC aborts the access and returns an error response back on the system bus. |                       |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Disable abort counter |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Enable abort counter  |
| 13      | RDYPOL   | ARDY Polarity.<br>The SMC_B3CTL.RDYPOL bit selects the polarity (active high or low) for the SMC_ARDY pin, if enabled (SMC_B3CTL.RDYEN =1). When the SMC samples the SMC_ARDY pin in the selective active state, the transaction completes.                                                                                                                                                                                                                                  |                       |

## Bank 3 Timing Register

The SMC\_B3TIM register configures bank 3 read and write access, setup, and hold timing for this bank. Note that read and write timing configurations are independent and may differ.

**SMC\_B3TIM: Bank 3 Timing Register - R/W**

Reset = 0x0101 0101

Bank 3 Extended Timing Register

The SMC\_B3ETIM register configures extensions to access times and idle times, augmenting the setup, hold, and access times configured with the SMC\_B3TIM register.

# 10 L2 Memory Controller (L2CTL)

The L2 memory controller is a system crossbar slave with multiple SCB ports that access banks of RAM and/or ROM. These interfaces and the memory subsystem run at the L2CLK frequency. The L2 memory controller also has a bus interface to provide access to the L2 controller's control and status registers. Each bank of L2 RAM memory is protected by ECC (error correction and control) logic which ensures that single bit errors can be corrected and multi-bit errors can be detected. For each 32KB bank, a 4Kx14 bits ECC RAM stores the parity bits.

## L2 Memory Controller Functional Description

The L2 memory domain is a unified instruction and data memory and can hold any mixture of code and data required by the system design. The L2 memory domain is accessible by both Blackfin cores through a dedicated 64-bit interface. It operates at half the frequency of the cores. The processor features 256K bytes of L2 SRAM which is ECC-protected and organized in eight banks. Individual banks can be made private to any of the cores or the DMA subsystem. There is also a 32K-byte single-bank ROM in the L2 domain. It contains boot code and safety functions.

## L2CTL Register List

The internal L2 memory controller (L2CTL) includes the controls to manage each L2 memory bank independently. This controller supports ECC and non-ECC operation with support for error tracking (by address or bus ID) and support for error type determination. A set of registers govern L2CTL operations. For more information on L2CTL functionality, see the L2CTL register descriptions.

**Table 10-1:** L2CTL Module Registers

| Name           | Description                    |
|----------------|--------------------------------|
| L2CTL_CTL      | Control Register               |
| L2CTL_ACTL_C0  | Access Control Core 0 Register |
| L2CTL_ACTL_C1  | Access Control Core 1 Register |
| L2CTL_ACTL_SYS | Access Control System Register |
| L2CTL_STAT     | Status Register                |

**Table 10-1:** L2CTL Module Registers (Continued)

| Name           | Description                   |
|----------------|-------------------------------|
| L2CTL_RPCR     | Read Priority Count Register  |
| L2CTL_WPCR     | Write Priority Count Register |
| L2CTL_RFA      | Refresh Address Register      |
| L2CTL_ERRADDR0 | ECC Error Address 0 Register  |
| L2CTL_ERRADDR1 | ECC Error Address 1 Register  |
| L2CTL_ERRADDR2 | ECC Error Address 2 Register  |
| L2CTL_ERRADDR3 | ECC Error Address 3 Register  |
| L2CTL_ERRADDR4 | ECC Error Address 4 Register  |
| L2CTL_ERRADDR5 | ECC Error Address 5 Register  |
| L2CTL_ERRADDR6 | ECC Error Address 6 Register  |
| L2CTL_ERRADDR7 | ECC Error Address 7 Register  |
| L2CTL_ET0      | Error Type 0 Register         |
| L2CTL_EADDR0   | Error Type 0 Address Register |
| L2CTL_ET1      | Error Type 1 Register         |
| L2CTL_EADDR1   | Error Type 1 Address Register |

## ADSP-BF60x L2CTL Interrupt List

**Table 10-2:** ADSP-BF60x L2CTL Interrupt List

| Description      | ID | DMA Channel | Sensitivity |
|------------------|----|-------------|-------------|
| L2CTL0 ECC Error | 4  |             | LEVEL       |

## L2 Memory Controller Block Diagram

The L2 Controller has 2 system crossbar ports. Port 0 is a 64-bit interface that handles core traffic. Port 1 is a 32-bit interface that connects through DMA access. Each port has a read channel and a write channel. Additionally, the read channel has a read address channel and a read data channel. Similarly, the write channel has write address, write data and write response channels.

**Figure 10-1:** L2 Memory Controller Block Diagram

RAM is organized in multiple banks, and each bank has 32K Bytes of data. Within each bank, data is organized into 4096 words, with each word comprising 64 bits + 14 bits of ECC. ROM memory does not contain any ECC bits. All access to L2 memories (both reads and writes) is always 64 bits in width. To support 8-, 16- and 32-bit writes, the controller generates a write mask.

## L2 Memory Controller Architectural Concepts

The following sections describe L2 memory controller architecture features, such as access characteristics, access ordering, locked access, and cache support.

### Access Characteristics

The L2 controller interface converts all 8-, 16- and 32-bit accesses to 64-bit accesses. Additionally, 8-, 16- and 32-bit bursts are converted to an equivalent internal 64-bit access. For example, a 64-bit address-aligned burst of 8-bit accesses of burst length 8 are converted to a single 64-bit access.

The L2 controller supports restriction of both core and DMA write accesses to a particular memory bank. The write access by a port to a particular RAM bank can be disabled by setting the appropriate bank write disable bit in that port's L2\_ACTLx register. Illegal access attempts generate an error response.

Memory writes complete in a single L2CLK cycle while reads complete in two cycles.

**Figure 10-2: RAM/ROM Read Timing**

## Cache Support

The L2 memory controller does not provide cache support.

## L2 Read/Write Latency and Throughput

The L2 memory design is optimized for burst access at the crossbar interface. Write data of 8/16/32-bit is buffered and converted to equivalent 64-bit access. This conversion creates modulo-32-bit writes if the starting addresses are 32-bit aligned. A single 8- or 16-bit access, or a non-32-bit address-aligned 8-bit or 16-bit burst access to an ECC-enabled bank creates an additional latency of two L2CLK cycles. No extra latency is seen if ECC is disabled.

**NOTE:** Continuous 8/16-bit core access to an ECC-enabled L2 bank is not recommended from a throughput perspective.

If two cores simultaneously try to access L2 for the same kind of access (both read or both write), even to different banks, only one core access is allowed at a time, as there is only 1 read port and 1 write port shared between the cores. However, if one core issues a write and the other issues a read, then access can proceed simultaneously, and inside L2 there is no extra latency, as long as the accesses are to different banks (assuming DMA is also to a non-conflicting bank).

If a core and DMA both access the same bank, then the best access rate that DMA can achieve is one 64-bit access in every three L2CLK cycles during the conflict period. This is achieved by programming the L2CTL\_RPCR.RPC0 and L2CTL\_WPCR.WPC0 bits to 0, while programming the L2CTL\_RPCR.RPC1 and the L2CTL\_WPCR.WPC1 bits to 1.

## Arbitration and Priority

Each bank of L2 RAM/ROM has an arbiter which receives requests from the two crossbar ports. The arbiters for all RAM banks are identical, but the ROM arbiter is simpler in that it only deals with read channels.

The RAM arbiter can receive four requests from the SCB ports (two read channel requests and two write channel requests), as well as a refresh request. Requesting channels are granted depending on their priority. The grants are valid for a particular cycle for writes and address reads, and valid for the next cycle for data reads.

Each arbiter follows a fixed priority scheme for giving grants when more than one channel requests the same bank. The arbiter also supports priority elevation through Urgent Priority requests.

The table below shows the priority for fixed priority mode (with urgent priority disabled) for each SCB channel.

**Table 10-3:** Fixed Priority

| Channel              | Priority Level |
|----------------------|----------------|
| L2 Refresh Request   | 5 (highest)    |
| Port 0 Read Channel  | 4              |
| Port 0 Write Channel | 3              |
| Port 1 Read Channel  | 2              |
| Port 1 Write Channel | 1 (lowest)     |

The arbiters also support priority elevation for a particular channel that has been starved of grants for a very large number of L2CLK cycles. If a channel does not get a grant for “N” cycles after its request, then that channel can elevate the priority of its request by issuing a urgent priority request. This causes that particular channel to become the highest priority master for the next grant cycle (this is pipelined arbitration for urgent priority). The number of cycles “N”, after which the priority is elevated, can be programmed for each channel separately using the L2CTL\_RPCR and L2CTL\_WPCR registers.

If there is an access conflict between the core and DMA to the same memory bank in the fixed priority arbitration scheme, with core activity always prioritized over DMA activity, and with the pipelined implementation of urgent priority, the best grant rate DMA can achieve is 1 in 3 L2CLK cycles during the conflict period. This can be achieved by programming L2CTL\_RPCR.RPCx and L2CCTL\_WPCR.WPCx appropriately.

Urgent priority requests can be disabled by setting L2CTL\_CTL.DISURP bit. This disables the urgent priority requests for all port channels. Each channel can also be prevented from raising the urgent priority request through the priority count register for the specific channel. However, there is no support for disabling urgent priority for a specific memory bank arbiter.

**Table 10-4:** Fixed Priority With Priority Elevation

| Channel                             | Priority Level |
|-------------------------------------|----------------|
| L2 Refresh Request                  | 9 (highest)    |
| Port 0 Read Channel Urgent Request  | 8              |
| Port 0 Write Channel Urgent Request | 7              |
| Port 1 Read Channel Urgent Request  | 6              |
| Port 1 Write Channel Urgent Request | 5              |
| Port 0 Read Channel Normal Request  | 4              |
| Port 0 Write Channel Normal Request | 3              |
| Port 1 Read Channel Normal Request  | 2              |
| Port 1 Write Channel Normal Request | 1 (lowest)     |

## L2 Memory Controller Event Control

The following sections describe L2 memory controller event control features, such as error response.

A bus error is signaled under any of the following conditions.

- A write access to ROM address space
- A read/write access to reserved address space
- A write access (including a TESTSET) to a restricted memory bank
- An ECC multi-bit error in an ECC enabled bank. A non-modulo32-bit write to an ECC enabled bank can also potentially create a bus error response due to an ECC multi-bit error. This is because the L2 controller implements a 32-bit ECC, and therefore a non-modulo32-bit write results in a read. This read may create multi-bit errors even if the memory was initialized.

Bus error notifications are stored in the L2CTL\_STAT register, and addresses that generated the error on a given port are stored in that port's L2CTL\_EADDRx register. The details of the error are stored in a port's L2CTL\_ETx register.

## L2CTL Register Descriptions

L2 Memory Controller (L2CTL) contains the following registers.

**Table 10-5:** L2CTL Module Registers

| Name           | Description                    |
|----------------|--------------------------------|
| L2CTL_CTL      | Control Register               |
| L2CTL_ACTL_C0  | Access Control Core 0 Register |
| L2CTL_ACTL_C1  | Access Control Core 1 Register |
| L2CTL_ACTL_SYS | Access Control System Register |
| L2CTL_STAT     | Status Register                |
| L2CTL_RPCR     | Read Priority Count Register   |
| L2CTL_WPCR     | Write Priority Count Register  |
| L2CTL_RFA      | Refresh Address Register       |
| L2CTL_ERRADDR0 | ECC Error Address 0 Register   |
| L2CTL_ERRADDR1 | ECC Error Address 1 Register   |
| L2CTL_ERRADDR2 | ECC Error Address 2 Register   |
| L2CTL_ERRADDR3 | ECC Error Address 3 Register   |
| L2CTL_ERRADDR4 | ECC Error Address 4 Register   |
| L2CTL_ERRADDR5 | ECC Error Address 5 Register   |
| L2CTL_ERRADDR6 | ECC Error Address 6 Register   |
| L2CTL_ERRADDR7 | ECC Error Address 7 Register   |
| L2CTL_ET0      | Error Type 0 Register          |

Table 10-5: L2CTL Module Registers (Continued)

| Name         | Description                   |
|--------------|-------------------------------|
| L2CTL_EADDR0 | Error Type 0 Address Register |
| L2CTL_ET1    | Error Type 1 Register         |
| L2CTL_EADDR1 | Error Type 1 Address Register |

Control Register

The L2CTL\_CTL register includes a write protection bit, enables L2 banks, and selects mapping of banks (as ECC RAM or data RAM).

L2CTL\_CTL: Control Register - R/W

Reset = 0x0000 0000

Figure 10-3: L2CTL\_CTL Register Diagram

**Table 10-6:** L2CTL\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | Lock.<br>If the global lock bit is set (SPU_CTL_GLCK bit =1) and the L2CTL_CTL.LOCK bit is set, the L2CTL_CTL register is read only (locked). |
|         |          | 0                      Unlock                                                                                                                 |
|         |          | 1                      Lock                                                                                                                   |
| 16      | DISURP   | Disable Urgent Request Priority.<br>The L2CTL_CTL.DISURP disables urgent request priority mode for all L2 banks.                              |
|         |          | 0                      Enable URP                                                                                                             |
|         |          | 1                      Disable URP                                                                                                            |

## Read Priority Count Register

The L2CTL\_RPCR register stores the count value to be used for priority elevation for bus read channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of L2CLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus read channel. A best practice is to program this register before initiating an L2 access.

**L2CTL\_RPCR: Read Priority Count Register - R/W**

Reset = 0x0000 0f0f

**Table 10-11:** L2CTL\_RPCR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                               |
|---------|----------|-------------------------------------------------------------------------------------------------------|
| 15:8    | RPC1     | Read Priority Count 1.<br>The L2CTL_RPCR.RPC1 bits hold the priority count for L2 bus read channel 1. |
| 7:0     | RPC0     | Read Priority Count 0.<br>The L2CTL_RPCR.RPC0 bits hold the priority count for L2 bus read channel 0. |

## Write Priority Count Register

The L2CTL\_WPCR register stores the count value to be used for priority elevation for bus write channels. If a bus channel is not granted access from the bank arbiter, the channel waits for the programmed number of L2CLK cycles, before the request is elevated to a high priority request. If a priority count value is programmed as zero for a channel, that channel does not raise the urgent priority request.

This is a read/write register, but a new value in the corresponding field must be written only when there are no outstanding transactions on the corresponding bus write channel. A best practice is to program this register before initiating an L2 access.

| Bit No. | Bit Name | Description/Enumeration                                                                                 |
|---------|----------|---------------------------------------------------------------------------------------------------------|
| 15:8    | WPC1     | Write Priority Count 1.<br>The L2CTL_WPCR.WPC1 bits hold the priority count for L2 bus write channel 0. |
| 7:0     | WPC0     | Write Priority Count 0.<br>The L2CTL_WPCR.WPC0 bits hold the priority count for L2 bus write channel 1. |

Refresh Address Register

The L2CTL\_RFA register stores the refresh address value. When this register is written, L2 initiates an atomic read-write operation to the address value written into the register. This is a read/write register, but a new value in the corresponding field has to be written only when there are no outstanding refresh request pending (L2CTL\_STAT.RFRS =0). If a write occurs while a request is pending, the L2CTL generates a bus error, and the write does not take effect.

**L2CTL\_RFA: Refresh Address Register - R/W**

Reset = 0xc808 0000

**Figure 10-10:** L2CTL\_RFA Register Diagram

**Table 10-13:** L2CTL\_RFA Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                         |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:18   | ADDRHI   | Address High.<br>The L2CTL_RFA.ADDRHI bits hold the high 16-bits of the L2 refresh address. Note that the upper 14 bits are hard-coded to the upper bits of the L2 address map. |
| 17:0    | ADDRLO   | Address Low.<br>The L2CTL_RFA.ADDRLO bits hold the low 16-bits of the L2 refresh address. Note that the lowest three bits are do not care.                                      |

## ECC Error Address 0 Register

The L2CTL\_ERRADDR0 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL\_STAT.ECCERR0) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

| 31:0    | VALUE    | ERRADDR Value.<br>The L2CTL_ERRADDR0.VALUE bits hold the address containing the ECC double bit error. |

ECC Error Address 1 Register

The L2CTL\_ERRADDR1 register holds the address containing an ECC multi-bit error for the corresponding bank. The L2CTL updates this register only if the bank's status bit (L2CTL\_STAT.ECCERR1) is cleared. After the bank's status bit is set for an error, further errors in the same bank are not detected until a W1C clears the status bit.

|---------|----------|-------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | ERRADDR Value.<br>The L2CTL_ERRADDR7.VALUE bits hold the address containing the ECC double bit error. |

## Error Type 0 Register

The L2CTL\_ET0 register holds information about the error transaction that has occurred on the bus for the corresponding L2 bus port. This register is updated only if the corresponding error status bit L2CTL\_STAT.ERR0 is cleared. After the status bit is set for an error, further errors do not update the L2CTL\_ET0 register until a W1C clears the corresponding status bit. If read and write access errors occur simultaneously, the L2CTL\_ET0 captures the write access error, keeping in sync with the error address register (L2CTL\_EADDR0).

## BF60x-Specific Information

The L2CLK runs at the same rate as SYSCLK.

The L2 memory subsystem has 2 SCB ports accessing 256 KB of RAM in 8 banks and 32 KB of ROM in a single bank.

## L2 Memory Controller ADSP-BF60x Throughput

**Table 10-26:** ADSP-BF60x Throughput

| Master     | Condition                                                                                                                                                                                                                                                                                                                                 | Core Throughput (MBPS) | DMA Throughput (MBPS) |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|-----------------------|
| Core Read  | Data Cache – burst read (cache fill) single core, data cache enabled. Instruction execution is from L1. Cache fill results in L2 burst access.                                                                                                                                                                                            | 540                    | N/A                   |
| Core Read  | Data Cache – dual burst read single core (with port preference) (cache fill).                                                                                                                                                                                                                                                             | 940                    | N/A                   |
| Core Read  | Instruction Cache – burst read, single core. Execution from L2 with instruction caching enabled.                                                                                                                                                                                                                                          | 550                    | N/A                   |
| Core Read  | Instruction Cache and data cache enabled – burst read, single core. Execution from L2 with data access also from L2. Here the instruction and data use must be aligned in such a way that an instruction miss is immediately followed by a data cache miss in the same instruction. This results in back-to-back burst read access to L2. | 666                    | N/A                   |
| Core Write | Data Cache – burst write (write back), single core, cache enabled                                                                                                                                                                                                                                                                         | 1028                   | N/A                   |
| Core Write | Non data cache – single write, cache disabled, single writes to L2, single core.<br>(1000 MBPS achieved by running in higher interrupt level)                                                                                                                                                                                             | 800, 1000              | N/A                   |
| DMA Read   | No conflict in the memory bank, multiple DMAs initiated to use the same bank, DDE burst length = 8                                                                                                                                                                                                                                        | N/A                    | 880                   |
| DMA Read   | No conflict in the memory bank, multiple DMAs initiated to use the same bank, DDE burst length = 4                                                                                                                                                                                                                                        | N/A                    | 800                   |
| DMA Read   | No conflict in the memory bank, multiple DMAs initiated to use the same bank, DDE burst length = 2                                                                                                                                                                                                                                        | N/A                    | 666                   |
| DMA Write  | No conflict in the memory bank, multiple DMAs initiated to use the same bank, DDE burst length = 8                                                                                                                                                                                                                                        | N/A                    | 880                   |

**Table 10-26:** ADSP-BF60x Throughput (Continued)

| Master    | Condition                                                                                                 | Core Throughput (MBPS) | DMA Throughput (MBPS) |

| Core/DMA  | Core and DMA writing to the same memory bank with RPC0/WPC0 = 0 and RPC1/WPC1 = 1, DDE burst length = 8   | 1340                   | 670                   |

# 11 Dynamic Memory Controller (DMC)

The dynamic memory controller (DMC) provides a glueless interface between DDR2/LPDDR SDRAMs and the system crossbar interface (SCB). The DMC enables execution of instructions from, as well as transfer of data to and from, DDR2 SDRAM as well as LPDDR SDRAM.

The DMC is partitioned in a manner that allows reconfiguration and maintainability. The memory access protocol state machine along with JEDEC standard specific logic is embedded in the “protocol controller”. An access and operation re-ordering mechanism is incorporated as an “efficiency controller”. An SCB slave interface is provided to interface with the on-chip interconnect. This interface results in an efficient slave implementation owing to its out-of-order transaction capabilities. The control and status registers present in the DMC controller can be accessed using the MMR access bus.

The DMC supports access to the external memory by core and DMA accesses. The external memory address space is divided into four banks.

## DMC Register List

The double data rate-synchronous DRAM (DMC) module provides an interface to external SDRAM. This interface support DDR2 and LPDDR operations. A set of registers govern DMC operations. For more information on DMC functionality, see the DMC register descriptions.

**Table 11-1:** DMC Module Registers

| Name        | Description                 |
|-------------|-----------------------------|
| DMC_CTL     | Control Register            |
| DMC_STAT    | Status Register             |
| DMC_EFFCTL  | Efficiency Control Register |
| DMC_PRI0    | Priority ID Register        |
| DMC_PRIOMSK | Priority ID Mask Register   |
| DMC_CFG     | Configuration Register      |
| DMC_TR0     | Timing 0 Register           |
| DMC_TR1     | Timing 1 Register           |

**Table 11-1:** DMC Module Registers (Continued)

| Name         | Description                          |
|--------------|--------------------------------------|
| DMC_TR2      | Timing 2 Register                    |
| DMC_MSK      | Mask (Mode Register Shadow) Register |
| DMC_MR       | Shadow MR Register                   |
| DMC_EMR1     | Shadow EMR1 Register                 |
| DMC_EMR2     | Shadow EMR2 Register                 |
| DMC_EMR3     | Shadow EMR3 Register                 |
| DMC_DLLCTL   | DLL Control Register                 |
| DMC_PHY_CTL1 | PHY Control 1 Register               |
| DMC_PHY_CTL3 | PHY Control 3 Register               |
| DMC_PADCTL   | PAD Control Register                 |

## ADSP-BF609 specific Register and bit settings

1. Bits 6, 7, 24, and 26 of the DMC\_PHY\_CTL3 register all need to be set to 1.
2. DMC\_DLLCTL register needs to be set to 0x54B. This keeps the default reset values and programs DATACYC to a value of 5.

## DMC Features

The DMC includes a protocol controller that supports JESD79-2E compatible double data rate (DDR2) SDRAM and JESD209A low power DDR (LPDDR) SDRAM devices.

The dynamic memory controller features are listed below.

- Provides 16-bit data interface to SDRAM devices
- Supports a single external rank (one chip select)
- Supports burst lengths of 4 and 8 words
- Provides page hit detection to support multiple column accesses to the same row
- User specified active, precharge and refresh commands.

- Programmable SDRAM access timing parameters
- Enables automatic refresh generation with programmable refresh intervals.
- Self-refresh mode to reduce system power consumption.

The DDR2 features are:

- 256M bit to 2G bit device sizes
- SDRAM data width of 16 (x16 devices only)
- Support for additive latency
- Support for ODT

The LPDDR features are:

- 64M bit to 2G bit device sizes
- SDRAM data width of 16 (x16 devices only)
- Support for deep power down mode
- PHY DLL calibration block
- DDR2 MEMIO I/O buffers
- Efficient transaction processing to improve throughput and bandwidth using:
  - Software programmable SCB IDs to allow SCB ID based priority
  - The ability to postpone up to eight auto-refresh commands
  - Software selectable closed page scheme on a per bank basis
  - Simple transaction scheduling mechanism to reduce read – write turnaround frequency on the memory bus
  - Accesses with the same SCB ID are scheduled back to back to take advantage of same page access in SDRAM
- Create parameters in the SCB slave interface with integrated buffers that support out of order transaction processing
- 

## Feature Exclusions

The DMC exclusions are as follows:

For DDR2:

- 4-bit and 8-bit wide DDR2 DRAM memories are not supported.
- OCD is not supported.
- Burst interleaved accesses are not supported.

For LPDDR:

- 32-bit wide LPDDR memory devices are not supported.
- Status register read (SRR) is not supported
- Sampling the optional Temperature output (TQ) signal is not supported.
- Clock Stop mode is not supported
- Bursts of 2 and 16 words are not supported.
- No support for BURST\_TERMINATE command.
- Dual-die, two CS# and two CKE packages are not supported.

## Functional Description

The Dynamic Memory Controller consists of master and slave interfaces, a protocol controller, and an efficiency controller. These function of these interfaces and controllers are described in the following sections.

### DMC Protocol Controller

The DDR2/LPDDR SDRAM protocol controller translates memory access requests from the SCB (system crossbar) interface to JEDEC protocol specific transactions used by DDR2/LPDDR SDRAM devices.

The protocol controller ensures that the various timing parameters are met before reading and writing the SDRAM. The controller also performs the SDRAM initialization sequence as mandated by the standard. The protocol controller is capable of issuing reads and writes and it can precharge a row in a bank, activate a row in a bank, and also put the SDRAM devices in self refresh and power down.

The protocol controller takes mode register writes from the MMR interface and translates them into mode register writes to SDRAM. Writing into the mode register is restricted via a mask register.

## DMC Efficiency Controller

The efficiency controller controls the ordering of transfers buffered in the read and write command buffers. It attempts to order transfers to optimize the available memory bandwidth. A number of schemes can be used to increase the throughput.

### Read/Write Turnaround

Read/Write turnaround reduces read – write turnaround on the memory bus and is the default method for optimizing bandwidth.

If read and write commands are outstanding in their respective buffers, the state of the efficiency controller determines the direction of the next transfer. When the controller is in the read state, and if both read and write commands are pending, write commands are given priority. Similarly, if the controller is in the write state, and if both read and write commands are pending, read commands are given priority. This ensures that the DMC does not perform transfers in a single direction continuously.

If read commands are outstanding in the read command buffer, a snapshot of the entries is taken. Commands that have the same SCB ID are scheduled in the order in which they were received. When the transfers complete, they are removed from the snapshot. The remaining transfers are scheduled in the order in which they appear in the buffer (0, 1, 2, and 3). After all transactions in the snapshot are complete, the controller moves to the write command buffer.

If write commands are outstanding, a snapshot of all valid entries is taken. A valid write entry is one that has the required amount of data available in the write buffer. Commands are scheduled in the order in which they appear in the buffer (0, 1, 2, and 3). After all transactions in the snapshot are complete they are moved to the read command buffer.

For writes and reads that have a SCB burst that is larger than the DDR2 burst length, one SCB burst is divided into several DDR2 bursts. As soon as the required amount of data is available for a DDR2 burst, a write command is scheduled at the protocol controller. Because of write data interleaving, subsequent SCB data continues to be buffered. If data for the next DDR2 burst is not available for an entry in the snapshot after the first pass is complete, the controller does not wait for the data to become available and moves on to the read snapshot.

For example assume that addresses RD1 and RD2 are present in the read buffer and WR1 and WR2 are present in the write buffer. Each of these addresses has a different SCB ID and the efficiency controller is in the write state.

1. The efficiency controller looks into the read buffer, takes a snapshot of all the commands and prepares to send the commands RD1 and RD2 to the protocol controller.
2. The efficiency controller remembers the location in the buffer where these transactions reside (assume locations 1 and 3). It picks location 1 (RD1) to start transfers at the protocol controller.
3. While this transfer happens, if RD3 arrived at location 2, it is ignored for the current snapshot.

4. After RD1 is finished, the controller moves to location 3 (RD2). Once RD2 completes, the controller moves to the write buffers.
5. While the reads occur, WR3 arrives in the WR address buffer. However, since the interleaving depth is only two, WR1 and WR2 data arrive but WR3's data is still being buffered and the required amount of data is not available. In this case, WR1 and WR2 make it to the snapshot as they are valid and have data ready to be sent. Even though WR3 data may arrive during the transfer of WR1 and WR2, it is only considered in the next snapshot.
6. After WR1 and WR2 are complete, the controller moves to the read buffer.
7. Finally, if WR1 requires two bursts through DDR2 and WR2 requires only one, if all data for WR1 is available, the two DDR2 bursts of WR1 are performed back-to-back before completing WR2. However, if only one DDR2 burst of data is available for WR1, the first DDR2 burst of WR1 is performed, followed by WR2. Then the efficiency controller returns to finish the rest of WR1. If WR1 data is not available, the controller does not wait in the write state and moves to the read buffer.

## Closed Page Per Bank

The DER\_EFFECTL register provides per-bank granularity for closing pages. If software determines that most accesses to a given bank in memory always result in a missed page, the PREC\_BANK bit corresponding to the required bank can be set to close the row after every transfer. This proactive step may result in reduced thrashing and increases memory throughput.

## SCB ID Based Priority

The primary goal of the dynamic memory controller is to improve sustainable memory system bandwidth so that the average request service time can be reduced. However, to service critical requests from any master in the system, a mechanism to elevate priority of a given access is provided. The DMC priority ID register (DMC\_PRI0) can be programmed with up to two SCB IDs whose priority is elevated in the default setup described in [Read/Write Turnaround](#).

After every access in a snapshot, the command buffers are searched to determine whether a command's ID matches with the ID programmed in the DMC\_PRI0 register. If a match occurs and the direction of the access (for example write) is the same as the direction of the snapshot (write), then the priority SCB ID access is sent before sending the subsequent access in the snapshot.

As an alternative to providing priority to a specific SCB ID, if a number of IDs from the same master require priority, the DMC priority mask ID register (DMC\_PRIOMSK) can be programmed so that the corresponding bits are 0. A combination of the DMC\_PRI0 register and the DMC\_PRIOMSK register can then be used to elevate the priority of a select few or all IDs that belong to a master (by default, none of the IDs are prioritized).

The following are a few possibilities

- The `PRI0_ID1_MASK` field of the `DMC_PRIOMSK` register is set to 0000. If a single ID (7234) needs priority, the `PRI0_ID1_MASK` field should be set to FFFF and the `PRI0_ID1` field of the `DMC_PRI0` register is set to 7234
- If the `PRI0_ID1_MASK` field is set to FFFE, the SCB IDs 7234 and 7235 are given priority.
- If the `PRI0_ID1_MASK` field is set to FFFC, the SCB IDs 7234, 7235, 7236 and 7237 are given priority.
- If two transactions with priority are outstanding with one being a read and the other being a write, the priority transaction that does not change the direction of the DMC access gets priority.
- The other priority transaction is handled at the beginning of the next snapshot. For example, if a write snapshot is in progress, the write priority transaction is sent. The read priority transaction is sent at the beginning of the next read snapshot.

**NOTE:** SCB-ID-based priority should be used judiciously because it can significantly reduce the throughput of the DMC.

## Delaying up to Eight Auto-Refresh Commands

This method is used to ensure that auto-refresh does not come in the way of any critical data transfers. Up to eight auto-refresh commands can be accumulated in the DMC and the exact number of auto-refresh commands can be programmed using the `NUM_REF` bit in the DMC efficiency control register.

After the first refresh command is accumulated, the DMC constantly looks for an opportunity to schedule a refresh command. When the SCB read and write command buffers become empty (which implies that no access is outstanding) for the programmed number of clock cycles (`IDLE_CYCLES`) in the DMC efficiency control register, the accumulated number of refresh commands are sent back to back to the DRAM.

After every refresh, the SCB command buffers are checked to ensure they stay empty. However, if the SCB command buffers are always filled, once the programmed number of refresh commands gets accumulated, the refresh operation is elevated to urgent priority and one refresh command is sent immediately. After this, the DMC continues to wait for an opportunity to send out refresh commands. If self-refresh is enabled, all pending refresh commands are given out only after that DMC enters into self-refresh.

## Page Interleaving and Bank Interleaving

In this method, the DMC provides a way to allow consecutive row accesses to fall into the same bank (bank interleaving) or into different bank (page interleaving). The `ADDR_MODE` bit in the `DMC_CTL` register indicates the interleaving option that the DMC is working on. By default, the DMC uses bank interleaving. If the `ADDR_MODE` bit is 1, the DMC uses page interleaving. Page misses in one addressing mode result in hits in the other addressing mode.

## System Crossbar Slave Interface

The system crossbar slave interface is used to move all data. The system crossbar interface accepts interleaved write transactions and is capable of sending out of order response. The read and write interfaces consist of buffers for address, data and control information transferred to/from the system crossbar bus.

The system crossbar interface transactions are sent to the SDRAM only after the SDRAM has been initialized. However if transactions arrive before or during initialization, they will be accumulated in the system crossbar interface and sent out to protocol controller once the initialization completes.

To increase throughput, system crossbar write response is sent out as soon as the final DDR2 burst is scheduled to be transferred into the SDRAM. However, if an auto-refresh needs to be performed, the scheduled write data will be sent only after the auto-refresh. There is a possibility of a delay of a maximum of 64 clock cycles from the moment write response is sent on system crossbar to the actual write of the data into SDRAM.

The system crossbar interface performs the following operations.

- Buffers read/write command requests from system crossbar bus.
- Processes the requests by converting them to protocol controller user interface transfers.
- Sends and receives data to/from the protocol controller.
- Creates suitable read/write response and sends read data back to the system crossbar bus.

The system crossbar slave interface supports the following:

- all burst lengths (1 – 16)
- incremental and wrap bursts
- data transfer sizes of 8, 16 or 32-bits
- arrival of write data before write address
- generation of error responses which includes
  - any access to un-implemented region of the external memory space
  - any access when the SDRAM is in self-refresh, power-down or deep power down (in case of LPDDR)
  - any access when the direct command interface is in operation

## Read/Write Command and Data Buffers

The system crossbar interface comprises of a four deep read command buffer and a four deep write command buffer. Up to four write commands and four read commands can be waiting for access to the SDRAM. The system crossbar write buffer is 32 deep. It can support write data interleaving of two. The system crossbar read buffer is 32 deep.

## Peripheral Bus Slave Interface

The peripheral bus slave interface connects the dynamic memory controller to the peripheral bus and provides a host controller with access to the registers. The peripheral bus slave interface supports the following features:

- read and write word accesses
- 32-bit data bus
- Ability to extend a transfer using PREADY
- Generation of PSLVERR when unimplemented registers are accessed or when read-only registers are written.

## Power Savings

This section discusses the suggested flow to enter and exit DDR self-refresh before and after the processor enters the HIBERNATE state.

For this procedure, the system is in normal operation and the EXT\_WAKE signal is high.

1. Put the SDRAM in self-refresh mode by setting the DMC\_CTL.SRREQ bit.

*STEP RESULT:* The DDR goes through the self-refresh entry sequence and enters the Self Refresh state.

*STEP RESULT:* The DMC\_STAT.SRACK bit is set.

*STEP RESULT:* The CKE pin is driven low by the controller when the DDR has entered Self-Refresh.

2. Read the DMC\_DLLCTL register to get the current DLL tap and calibration settings. This can be used later to quickly lock and start normal DDR operation. The values read are stored in the DPM registers.
3. Initialize the Power-On Reset Delay register to the appropriate values to count off the time required for core  $V_{DD}$  to reach a safe value when exiting the Hibernate state.
4. Enter the Hibernate state by following the procedure detailed in the DPM chapter. Hibernate is indicated by the EXT\_WAKE signal going low.
5. When EXT\_WAKE goes low, the part enters Hibernate state and remains here until brought out by this state through SYS\_PWRGD pin/counter expiry.
6. When a wake-up event occurs, first the EXT\_WAKE signal goes high.

*ADDITIONAL INFORMATION:* When core  $V_{DD}$  power reaches a proper value, the Core domain logic is reset. The DDR controller drives the input of the CKE pad low. When this counter reaches 0 a Counter Expiry signal is generated and Core  $V_{DD}$  is deemed to have reached a safe value. Now, the CKE pin which is driven by the DDR controller is released, so whatever is driven by the DDR controller (at this time driven to 0) at its input pin is driven out to the pads.

7. The DDR controller acts as if it has just come out of reset. The software should now program the `DMC_CTL.SRREQ` bit to write a 1. The `DMC_CTL.INIT` bit should not be set during this write, because starting an `INIT` sequence is not desired.

*ADDITIONAL INFORMATION:* The controller interprets this Self-Refresh request as a command to directly jump to the Self-Refresh state in the state machine.

*ADDITIONAL INFORMATION:* Once the DDR state machine goes to the Self-Refresh state, it should set up all the state variables and status indications to appropriate values. It should appear as though the state machine just entered a Self-Refresh state (as in step 2 above).

*ADDITIONAL INFORMATION:* Further, the `INIT_DONE` bit is now set to 1 (programs should not be performing an `INIT` now because it was already done before Hibernate) and also the `SRACK` bit is set to 1.

8. Software retrieves the DLL data stored in the HV domain and programs the `DMC_DLLCTL` register. This acts as a guess value for the DLL lock and DLL calibration and shortens the time taken to achieve DLL lock.
9. The software should poll for DLL lock status to go high and then clear the `SRREQ` bit in the DDR control register which kick starts a Self-Refresh exit process.
10. After Self-Refresh exit (indicated by the `DMC_STAT.SRACK` bit), start DLL calibration by writing into the `DMC_CTL.DLLCAL` bit. The number of reads required for calibration this time are less than normal power up (cold start) calibration, since the guess value for this has been programmed in the `DMC_DLLCTL` register.

*RESULT:*

Once the calibration process is complete, the `DMC_STAT.DLLCALDONE` bit is set. Normal operations to DDR memory can now start.

## DMC DMA

The DMC controller supports DMA-based transfers to and from external DDR2/LPDDR memory and internal memory.

The DMC DMA controller, part of the Distributed DMA Engines (DDE) that are dispersed through the infrastructure, connects to the system crossbar fabric.

Two DDEs are used for memory-to-memory DMA (MemDMA). One channel is the source channel, and the second, the destination channel.

DMA transfers on the processor can be descriptor-based or register-based. Register-based DMA allows the processor to directly program DMA control registers to initiate a DMA transfer. On completion, the control registers may be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. This sort of transfer allows the chaining together of multiple DMA sequences. In

descriptor-based DMA operations, a DMA channel can be programmed to automatically set up and start another DMA transfer after the current sequence completes.

Please refer to the DDE chapter for further details.

## DMC Programming Model

The dynamic memory controller contains five groups of memory mapped registers. These registers are accessed using the MMR access bus and are described below.

- Control and status registers. These registers control the various operation modes of the dynamic memory controller and also provide status.
- Timing parameter registers. The value programmed in these registers depends on the speed grade of DDR2 SDRAM device used.
- Mode register mirror registers - These shadow registers are copies of the mode registers residing in the SDRAM device.
- PHY control and status registers – These registers are used to control the operation of the PHY.
- PAD control registers – These registers are used to control the various aspects of the I/O pads.

The DMC control registers contain sensitive timing parameters and settings for the DDR SDRAM. These registers are programmed with values that are in the operating range of the DDR used.

Writing to reserved fields or writing any reserved values in register bits may cause the dynamic memory controller to function erroneously.

## Configuring the DMC

### *PREREQUISITE:*

After a processor's hardware or software reset, the DMC clocks are enabled. However the DMC must be configured and initialized before any data transfer can take place. Before programming the DMC and executing the power up (initialization) sequence, ensure that the clock to the SDRAM is enabled after the power has stabilized for the proper amount of time (as specified by the SDRAM specification).

1. Check to first ensure that the DMC is idle and not in the midst of any activity.
2. Please the DMC in self-refresh mode.
3. Program the PLL frequency to a new value (if required).

4. Wait the appropriate number of core cycles to ensure that the DLL has locked.
5. Bring the DMC out of self-refresh mode.
6. Program the DMC0\_CFG, DMC0\_CTL, DMC0\_TR0-2, DMC0\_MR, DMC0\_PHY\_CTL1 and DMC0\_PHY\_CTL3 registers to the appropriate values, to set proper SDRAM cycle timing options (eg.,  $t_{RAS}$ ,  $t_{RC}$ ,  $t_{RP}$ ,  $t_{RCD}$ ,  $t_{WR}$ ,  $t_{FAW}$  are some of the parameters).
7. Program the shadow registers DMC0\_EMR1-3, with the required burst length, CAS latency, additive latency and other parameters.
8. Finally, after these registers are programmed, write the `INIT` bit to the DMC control register (0x0004) to begin the power-up initialization sequence.
9. Wait for the SDRAM initialization sequence to complete.
10. Write the DMC\_PADCTL register with values that reflect the type of SDRAM connected to the processor. Specific bit fields within this register determine if the pad is operating in LPDDR mode or DDR2 mode. The drive strengths required at the pads can also be programmed in this register.

**Figure 11-1:** DMC Initialization Flow

System crossbar transactions that occur during or before initialization are accumulated by the DMC and sent to SDRAM once the SDRAM initialization and/or DLL calibration is complete.

### DLL Initialization

When initializing the DLL for the first time, it is important to follow the following steps:

- 1) Check for (MEMINITDONE & DLLCALDONE) in the DMC\_STAT register
- 2) If this is NOT set, set init bit in DMC\_CTL register and wait for (MEMINITDONE & DLLCALDONE) bits to be set in the DMC\_STAT register

3) If this is set:

- a) Enter into self-refresh
- b) Change the clock frequency, as required
- c) Wait for DLL lock
- d) Exit self refresh
- e) Write new control register values
- f) Set init bit in DMC\_CTL register and poll the MEMINITDONE and DLLCALDONE bits within the DMC\_STAT register
- g) Write to the DMC\_DLLCTL register.

Note that for cases where the DDR2 interface has already been initialized (whether it is via an XML file loaded in during a debug session, or through code executed during the booting process), the user needs to perform second-time initialization as described above.

## DMC Register Descriptions

DDR (DMC) contains the following registers.

**Table 11-2:** DMC Module Registers

| Name        | Description                 |
|-------------|-----------------------------|
| DMC_CTL     | Control Register            |
| DMC_STAT    | Status Register             |
| DMC_EFFCTL  | Efficiency Control Register |
| DMC_PRI0    | Priority ID Register        |
| DMC_PRIOMSK | Priority ID Mask Register   |
| DMC_CFG     | Configuration Register      |
| DMC_TR0     | Timing 0 Register           |
| DMC_TR1     | Timing 1 Register           |

**Table 11-2:** DMC Module Registers (Continued)

| Name         | Description                          |
|--------------|--------------------------------------|
| DMC_TR2      | Timing 2 Register                    |
| DMC_MSK      | Mask (Mode Register Shadow) Register |
| DMC_MR       | Shadow MR Register                   |
| DMC_EMR1     | Shadow EMR1 Register                 |
| DMC_EMR2     | Shadow EMR2 Register                 |
| DMC_EMR3     | Shadow EMR3 Register                 |
| DMC_DLLCTL   | DLL Control Register                 |
| DMC_PHY_CTL1 | PHY Control 1 Register               |
| DMC_PHY_CTL3 | PHY Control 3 Register               |
| DMC_PADCTL   | PAD Control Register                 |

## Control Register

The DMC\_CTL register controls DMC modes, DLL calibration, and DRAM initialization.

**DMC\_CTL: Control Register - R/W**

Reset = 0x0000 0000

**Figure 11-2: DMC\_CTL Register Diagram**

**Table 11-3: DMC\_CTL Register Fields**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13      | DLLCAL   | DLL Calibration Start.<br>The DMC_CTL.DLLCAL bit starts the PHY DLL calibration sequence.<br>Note that this bit always reads as 0.                                                                                                                                                                                                                               |
|         |          | 0 No Effect                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1 Start PHY DLL Calibration                                                                                                                                                                                                                                                                                                                                      |
| 12      | PPREF    | Postpone Refresh.<br>The DMC_CTL.PPREF bit enables postponing the DMC's sending of auto-refresh commands. When enabled, the DMC accumulates refresh commands. The DMC_EFFECTL.NUMREF field selects the number of refresh commands that the DMC may accumulate. When disabled, the DMC_TR1.TREF field selects the interval for auto-refresh command distribution. |
|         |          | 0 Disable Postpone Refresh                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1 Enable Postpone Refresh                                                                                                                                                                                                                                                                                                                                        |

**Table 11-3:** DMC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:9    | RDTOWR   | Read-to-Write Cycle.<br>The DMC_CTL.RDTOWR bits select the number of cycles that the DMC adds when a write operation follows a read operation. Note that values 101 through 111 are reserved.                                                                                                                                          |
|         |          | 0      0 Cycles Added                                                                                                                                                                                                                                                                                                                  |
|         |          | 1      1 Cycle Added                                                                                                                                                                                                                                                                                                                   |
|         |          | 2      2 Cycles Added                                                                                                                                                                                                                                                                                                                  |
|         |          | 3      3 Cycles Added                                                                                                                                                                                                                                                                                                                  |
|         |          | 4      4 Cycles Added                                                                                                                                                                                                                                                                                                                  |
| 8       | ADDRMODE | Addressing (Page/Bank) Mode.<br>The DMC_CTL.ADDRMODE bit selects whether the DMC uses page or bank interleaving for addressing. When using page interleaving, the bank address bits follow the most significant column address bits. When using bank interleaving, the bank address bits follow the most significant row address bits. |
|         |          | 0      Bank Interleaving                                                                                                                                                                                                                                                                                                               |
|         |          | 1      Page Interleaving                                                                                                                                                                                                                                                                                                               |
| 6       | PREC     | Precharge.<br>The DMC_CTL.PREC bit enables pre-charge, which closes DRAM rows immediately after access. When disabled, all accesses result in the respective DRAM rows remaining open, until the DMC needs to close them.                                                                                                              |
|         |          | 0      No Effect                                                                                                                                                                                                                                                                                                                       |
|         |          | 1      Enable Precharge                                                                                                                                                                                                                                                                                                                |

**Table 11-3:** DMC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | DPDREQ   | Deep Power Down Request.<br>The DMC_CTL.DPDREQ bit enables deep powerdown mode if low power DMC operation is enabled (DMC_CTL.LPDDR = 1}). When the processor does not require the data stored in SDRAM (assume reset state of SDRAM), the DMC may put the SDRAM in deep powerdown mode. When the DMC is in deep powerdown, any data accesses cause the DMC to generate a bus error. |
|         |          | 0                      Disable Deep Powerdown                                                                                                                                                                                                                                                                                                                                        |
|         |          | 1                      Enable Deep Powerdown                                                                                                                                                                                                                                                                                                                                         |
| 4       | PDREQ    | Power Down Request.<br>The DMC_CTL.PDREQ bit enables powerdown mode. When the DMC is in powerdown, any data accesses cause the DMC to generate a bus error.                                                                                                                                                                                                                          |
|         |          | 0                      Disable Powerdown                                                                                                                                                                                                                                                                                                                                             |
|         |          | 1                      Enable Powerdown                                                                                                                                                                                                                                                                                                                                              |
| 3       | SRREQ    | Self Refresh Request.<br>The DMC_CTL.SRREQ bit enables self refresh mode. When the DMC is in self-refresh, any data accesses cause the DMC to generate a bus error.                                                                                                                                                                                                                  |
|         |          | 0                      Disable Self Refresh                                                                                                                                                                                                                                                                                                                                          |

| 2       | INIT     | Initialize DRAM Start.<br>The DMC_CTL.INIT bit starts the power up DRAM initialization sequence and DLL calibration sequence. Note that this bit always reads as 0.                                                                                                                                                                                                                  |
|         |          | 0                      No Effect                                                                                                                                                                                                                                                                                                                                                     |
|         |          | 1                      Start DRAM Initialization                                                                                                                                                                                                                                                                                                                                     |

**Table 11-3:** DMC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                           |
|---------|----------|-------------------------------------------------------------------------------------------------------------------|
| 1       | LPDDR    | Low Power DDR Mode.<br>The DMC_CTL.LPDDR bit selects whether the DMC operates in low power DDR mode or DDR2 mode. |
|         |          | 0                      DDR2 mode                                                                                  |
|         |          | 1                      LPDDR mode                                                                                 |

Status Register

The DMC\_STAT register indicates status for modes selected with the DMC\_CTL register and indicates status DMC operations.

**DMC\_STAT: Status Register - R/NW**

Reset = 0x0000 0001

**Figure 11-3:** DMC\_STAT Register Diagram

**Table 11-4:** DMC\_STAT Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                                                                             |
|---------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23:20   | PHYRDPHASE | PHY Read Phase.<br>The DMC_STAT.PHYRDPHASE bits indicate the latency after which the DMC may read from the PHY. Taking round trip delay into account, the DLL indicates the exact number of clock cycles after which the controller needs to read data. Values other than those shown are reserved. |
|         |            | 2      2 Clock Cycles Latency                                                                                                                                                                                                                                                                       |
|         |            | 3      3 Clock Cycles Latency                                                                                                                                                                                                                                                                       |
|         |            | 4      4 Clock Cycles Latency                                                                                                                                                                                                                                                                       |
|         |            | 5      5 Clock Cycles Latency                                                                                                                                                                                                                                                                       |
| 19:16   | PENDREF    | Pending Refresh.<br>The DMC_STAT.PENDREF bits indicate the number of pending auto-refresh commands. When the DMC is in low power DDR mode (DMC_CTL.LPDDR=1), the maximum value for DMC_STAT.PENDREF is 3.                                                                                           |
| 13      | DLLCALDONE | DLL Calibration Done.<br>The DMC_STAT.DLLCALDONE indicates that the PHY DLL calibration sequence is complete.                                                                                                                                                                                       |
|         |            | 0      No Status                                                                                                                                                                                                                                                                                    |
|         |            | 1      Completed PHY DLL Calibration                                                                                                                                                                                                                                                                |
| 5       | DPDACK     | Deep Powerdown Acknowledge.<br>The DMC_STAT.DPDACK bit indicates that deep powerdown mode is active. Note that this status is available in low power DDR mode (DMC_CTL.LPDDR=1) only.                                                                                                               |
|         |            | 0      Not in Deep Powerdown Mode                                                                                                                                                                                                                                                                   |
|         |            | 1      Deep Powerdown Mode Active                                                                                                                                                                                                                                                                   |

## Efficiency Control Register

The DMC\_EFFCTL register control DMC features that improve throughput efficiency. These include features such as auto-refresh management, pre-charge options, and write data options.

DMC\_EFFCTL: Efficiency Control Register - R/W

Reset = 0x0044 0000

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19:16   | NUMREF    | <p>Number of Refresh Commands.</p> <p>The <code>DMC_EFFCTL.NUMREF</code> bits select the number of auto-refresh commands that the DMC may accumulate if postpone refresh is enabled (<code>DMC_CTL.PPREF = 1</code>). The number of auto-refresh commands that may be accumulated depends on whether the DMC is in DDR2 or LPDDR mode as selected by the <code>DMC_CTL.LPDDR</code> bit. In LPDDR mode, the DMC may accumulate up to four auto-refresh commands. In DDR2 mode, the DMC may accumulate up to eight auto-refresh commands.</p> |
|         |           | 0 No Refresh Commands Accumulate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         |           | 1 1 Refresh Command May Accumulate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|         |            | 1      Enable Precharge Bank 1                                                                                                                                                                                                                    |
| 8       | PRECBANK0  | Precharge Bank 0.<br>The DMC_EFFCTL.PRECBANK0 bit enables precharge (closes the page) of bank 0 after each transfer if the DMC precharge feature is enabled (DMC_CTL.PREC =1).                                                                    |
|         |            | 0      Disable Precharge Bank 0                                                                                                                                                                                                                   |
|         |            | 1      Enable Precharge Bank 0                                                                                                                                                                                                                    |
| 7       | WAITWRDATA | Wait in Write Data Snapshot.<br>The DMC_EFFCTL.WAITWRDATA bit enables waiting in write snapshot if the DDR2 or LPDDR burst is not available for the transfer. If disabled, the DMC does not wait in write snapshot when the burst is unavailable. |
|         |            | 0      Disable Wait for Burst                                                                                                                                                                                                                     |
|         |            | 1      Enable Wait for Burst                                                                                                                                                                                                                      |

Table 11-5: DMC\_EFFCTL Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                                                               |
|---------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | FULLWRDATA | Wait for Full Write Data.<br>The DMC_EFFCTL.FULLWRDATA bit enables waiting until all data is available from the bus to start the DMC transfer. If disabled, the DMC does to wait for full write data, instead the DMC starts the transfer when DDR2 or LPDDR burst becomes available. |
|         |            | 0                      Disable Wait for Full Data                                                                                                                                                                                                                                     |
|         |            | 1                      Enable Wait for Full Data                                                                                                                                                                                                                                      |

Priority ID Register

The DMC\_PRIO register selects up to two internal bus master IDs for banks to receive elevated access priority by the DMC efficiency controller.

DMC\_PRIO: Priority ID Register - R/W

Reset = 0x0000 0000

Figure 11-5: DMC\_PRIO Register Diagram

Table 11-6: DMC\_PRIO Register Fields

| Bit No. | Bit Name | Description/Enumeration          |
|---------|----------|----------------------------------|
| 31:16   | ID2      | ID2 Requiring Elevated Priority. |
| 15:0    | ID1      | ID1 Requiring Elevated Priority. |

## Priority ID Mask Register

The DMC\_PRIOMSK register permits masking portions of up to two internal bus master IDs for banks to receive elevated access priority by the DMC efficiency controller. This masking provides for elevating the access priority of either a single ID or a range of IDs.

DMC\_PRIOMSK: Priority ID Mask Register - R/W

Reset = 0x0000 0000

Figure 11-6: DMC\_PRIOMSK Register Diagram

Table 11-7: DMC\_PRIOMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:16   | ID2MSK   | Mask for ID2.           |
| 15:0    | ID1MSK   | Mask for ID1.           |

## Configuration Register

The DMC\_CFG register selects SDRAM device specific parameters and selects the SDRAM interface width.

DMC\_CFG: Configuration Register - R/W

Reset = 0x0000 0000

Figure 11-7: DMC\_CFG Register Diagram

Table 11-8: DMC\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                         |                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| 15:12   | EXTBANK  | External Banks.<br>The DMC_CFG.EXTBANK bits select the number of external banks connected to the DMC. Note that all values other than those shown are reserved. |                             |
|         |          | 0                                                                                                                                                               | 1 External Bank             |
| 11:8    | SDRSIZE  | SDRAM Size.<br>The DMC_CFG.SDRSIZE bits select the size of individual SDRAM connected to the DMC. Note that all values other than those shown are reserved.     |                             |
|         |          | 0                                                                                                                                                               | 64M Bit SDRAM (LPDDR Only)  |
|         |          | 1                                                                                                                                                               | 128M Bit SDRAM (LPDDR Only) |
|         |          | 2                                                                                                                                                               | 256M Bit SDRAM              |

## Timing 0 Register

The DMC\_TR0 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC\_TR0 are in increments of clock cycle time ( $t_{CK}$ ).

**Table 11-9:** DMC\_TR0 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:28   | TMRD     | Timing Mode Register Delay.<br>The DMC_TR0.TMRD field selects the set-to-active timing parameter ( $t_{MRD}$ ), which is the number of clock cycles that occur after the mode registers in the SDRAM are set and before the next command is issued.      |
| 25:20   | TRC      | Timing Row Cycle.<br>The DMC_TR0.TRC field selects the active-to-active time ( $t_{RC}$ ), which is the minimum number of clock cycles that occur from an active command to the next active command in the same bank.                                    |
| 16:12   | TRAS     | Timing Row Active Time.<br>The DMC_TR0.TRAS field selects the active-to-precharge time ( $t_{RAS}$ ), which is the number of clock cycles that occur from an active command until a precharge command is allowed.                                        |
| 11:8    | TRP      | Timing RAS Precharge..<br>The DMC_TR0.TRP field selects the precharge-to-active time ( $t_{RP}$ ), which is the number of clock cycles that occur while the SDRAM recovers from a precharge command and becomes ready to accept the next active command. |
| 7:4     | TWTR     | Timing Write to Read.<br>The DMC_TR0.TWTR field selects the write-to-read delay time ( $t_{WTR}$ ), which is the number of clock cycles that occur from the last write data to the next read command.                                                    |
| 3:0     | TRCD     | Timing RAS to CAS Delay.<br>The DMC_TR0.TRCD field selects the RAS to CAS delay time ( $t_{RCD}$ ), which is the number of clock cycles that occur from an active command to a read/write assertion.                                                     |

## Timing 1 Register

The DMC\_TR1 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC\_TR1 are in increments of clock cycle time ( $t_{CK}$ ).

**DMC\_TR1: Timing 1 Register - R/W**

Reset = 0x0000 0000

**Figure 11-9:** DMC\_TR1 Register Diagram

**Table 11-10:** DMC\_TR1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:28   | TRRD     | Timing Read-Read Delay.<br>The DMC_TR1 . TRRD field selects the active-to-active time ( $t_{RRD}$ ), which is the minimum number of clock cycles occurring from a bank x active command to a bank y active command.                                                                                                                                                                                                                                                                                                                                            |
| 23:16   | TRFC     | Timing Refresh-to-Command.<br>The DMC_TR1 . TRFC field selects the refresh-to-active command delay ( $t_{RFC}$ ), which is the number of clock cycles required for the SDRAM to recover from a refresh signal to be ready to take the next command. It is also the number of clock cycles needed for the SDRAM to recover from executing one active command and ready to accept the next active command.                                                                                                                                                       |
| 13:0    | TREF     | Timing Refresh Interval.<br>The DMC_TR1 . TREF field selects the refresh interval time ( $t_{REF}$ ), which is the number of clock cycles occurring from one refresh command to the next refresh command. The actual timing of issuing a precharge command may be delayed by if the SDRAM is processing a normal access. However, the delay is not accumulative so there is no need to shorten the refresh interval to account for the memory access time. The non-accumulative refresh delay typically increases memory bandwidth by a few percentage points. |

## Timing 2 Register

The DMC\_TR2 register selects timing parameters for DMC operation to corresponding with parameters of the SDRAM device that is used in the system. The timing registers must be programmed to match the device for correct operation of the SDRAM and must be programmed before initializing the SDRAM. Note that all values for bit fields in DMC\_TR2 are in increments of clock cycle time ( $t_{CK}$ ).

**DMC\_TR2: Timing 2 Register - R/W**

Reset = 0x0000 0000

**Figure 11-10:** DMC\_TR2 Register Diagram

**Table 11-11:** DMC\_TR2 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 23:20   | TCKE     | Timing Clock Enable.<br>The DMC_TR2.TCKE field selects the CKE minimum pulsewidth ( $t_{CKE}$ ).                                              |
| 19:16   | TXP      | Timing Exit Powerdown.<br>The DMC_TR2.TXP field selects the exit powerdown to next valid command time ( $t_{XP}$ ).                           |
| 15:12   | TWR      | Timing Write Recovery.<br>The DMC_TR2.TWR field selects the write recovery time ( $t_{WR}$ ). Note that this parameter applies to LPDDR only. |
| 11:8    | TRTP     | Timing Read-to-Precharge.<br>The DMC_TR2.TRTP field selects the internal read to precharge time ( $t_{RTP}$ ).                                |

Table 11-11: DMC\_TR2 Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                   |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4:0     | TFAW     | Timing Four-Activated-Window.<br>The DMC_TR2.TFAW field selects the four-banks-activated window time ( $t_{FAW}$ ). No more than four SDRAM banks should be activated within this window. |

Mask (Mode Register Shadow) Register

The DMC\_MSK register permits masking (disabling) writes to the MR and EMRn registers in the SDRAM. When masked, writes to these registers go instead to shadow copies of these registers (DMC\_MR, DMC\_EMR1, DMC\_EMR2, and DMC\_EMR3), which are maintained within the DMC. When a shadow register's corresponding bit is unmasked (enabled), the DMC generates the MRS or EMRS command to transfer the contents of the shadow register (in the DMC) to the actual register (in the SDRAM).

DMC\_MSK: Mask (Mode Register Shadow) Register - R/W

Reset = 0x0000 0000

Figure 11-11: DMC\_MSK Register Diagram

Table 11-12: DMC\_MSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                       |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8       | MR       | Shadow MR Unmask.<br>The DMC_MSK.MR bit masks or unmasks writes to the MR register in the SDRAM. When masked, writes to this register instead go to the DMC_MR register. When unmasked, the DMC writes the DMC_MR value to the MR register in the SDRAM. After completing the write, the DMC clears this bit. |
|         |          | 0 Mask (Disable) Write to MR                                                                                                                                                                                                                                                                                  |
|         |          | 1 Unmask (Enable) Write to MR                                                                                                                                                                                                                                                                                 |

Shadow MR Register

The DMC\_MR register in the DMC shadows the MR register in the SDRAM when the DMC is in DDR2 mode or LPDDR mode (DMC\_CTL.LPDDR = 0 or = 1). If unmasked by the corresponding bit in the shadow mask register (DMC\_MSK.MR = 1), a write to DMC\_MR triggers a "mode register set" command on the memory interface. If masked, a write to DMC\_MR only updates the register in the DMC, not the register in the SDRAM.

DMC\_MR: Shadow MR Register - R/W

Reset = 0x0000 0000

## Shadow EMR1 Register

The `DMC_EMR1` register in the DMC shadows the EMR1 register in the SDRAM when the DMC is in DDR2 mode (`DMC_CTL.LPDDR=0`). Note that this register must not be used when the DMC is in LPDDR mode (`DMC_CTL.LPDDR=1`). If unmasked by the corresponding bit in the shadow mask register (`DMC_MSK.EMR1=1`), a write to `DMC_EMR1` triggers an extended "mode register set" command on the memory interface. If masked, a write to `DMC_EMR1` only updates the register in the DMC, not the register in the SDRAM.

DMC\_EMR1: Shadow EMR1 Register - R/W

Reset = 0x0000 0000

## Shadow EMR2 Register

The DMC\_EMR2 register in the DMC shadows the EMR2 register in the SDRAM when the DMC is in DDR2 mode (DMC\_CTL.LPDDR=0) and shadows the EMR register in the SDRAM when the DMC is in LPDDR mode (DMC\_CTL.LPDDR=1). If unmasked by the corresponding bit in the shadow mask register (DMC\_MSK.EMR2=1), a write to DMC\_EMR2 triggers an extended "mode register set" command on the memory interface. If masked, a write to DMC\_EMR2 only updates the register in the DMC, not the register in the SDRAM.

### DMC\_EMR2: Shadow EMR2 Register - R/W

Reset = 0x0000 0000

**Figure 11-14:** DMC\_EMR2 Register Diagram

**Table 11-15:** DMC\_EMR2 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                         |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | SRF      | High Temp. Self Refresh.<br>The DMC_EMR2.SRF bit enables the SDRAM's high temperature self refresh rate feature when the DMC is in DDR2 mode. (This bit is reserved in LPDDR mode.) For more information about this operation, see the data sheet for the SDRAM being used in your system.                                      |
|         |          | 0      1x Refresh Rate (0degC to 85degC)                                                                                                                                                                                                                                                                                        |
|         |          | 1      2x Refresh Rate (>85degC)                                                                                                                                                                                                                                                                                                |
| 6:5     | DS       | Drive Strength.<br>The DMC_EMR2.DS bits select the drive strength value when the DMC is in LPDDR mode. (These bits are reserved when the DMC is in DDR2 mode.) Note that all values other than those shown are reserved. For more information about this operation, see the data sheet for the SDRAM being used in your system. |
|         |          | 0      Full Drive Strength                                                                                                                                                                                                                                                                                                      |
|         |          | 1      1/2 Drive Strength                                                                                                                                                                                                                                                                                                       |
|         |          | 2      1/4 Drive Strength                                                                                                                                                                                                                                                                                                       |
|         |          | 3      3/4 Drive Strength                                                                                                                                                                                                                                                                                                       |
| 4:3     | TCSR     | Temp. Comp. Self Refresh.<br>The DMC_EMR2.TCSR bits select the temperature for applying temperature compensated self refresh when the DMC is in LPDDR mode. (These bits are reserved when the DMC is in DDR2 mode.) For more information about this operation, see the data sheet for the SDRAM being used in your system.      |
|         |          | 0      70 degree C (in LPDDR Mode)                                                                                                                                                                                                                                                                                              |
|         |          | 1      45 degree C                                                                                                                                                                                                                                                                                                              |

## Shadow EMR3 Register

The DMC\_EMR3 register in the DMC shadows the EMR3 register in the SDRAM when the DMC is in DDR2 mode (DMC\_CTL.LPDDR=0). Note that this register must not be used when the DMC is in LPDDR mode (DMC\_CTL.LPDDR=1). If unmasked by the corresponding bit in the shadow mask register (DMC\_MSK.EMR3=1), a write to DMC\_EMR3 triggers an extended "mode register set" command on the memory interface. If masked, a write to DMC\_EMR3 only updates the register in the DMC, not the register in the SDRAM.

### DMC\_EMR3: Shadow EMR3 Register - R/W

Reset = 0x0000 0000

**Figure 11-15:** DMC\_EMR3 Register Diagram

**Table 11-16:** DMC\_EMR3 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                   |
|---------|----------|-----------------------------------------------------------|
| 31:0    | RESERVED | Reserved.<br>All bits the DMC_EMR3 register are reserved. |

## DLL Control Register

The DMC\_DLLCTL register holds the programmable parameters associated with the DLLs within the DMC PHY.

# 12 Cyclic Redundancy Check (CRC)

The CRC peripheral is used to perform the Cyclic Redundancy Check (CRC) of the block of data that is presented to the peripheral. The peripheral provides a means to periodically verify the integrity of the system memory, the contents of memory-mapped registers (MMRs), or communication message objects, and it is based on a CRC32 engine that computes the signature of 32-bit data presented to the peripheral.

The dedicated hardware compares the calculated signature of the operation to a pre-loaded expected signature and if the two fail to match, the peripheral generates an error.

Data may be provided by the source channel of the memory-to-memory DMA channels and optionally forwarded to memory via the destination DMA channel. Alternatively, the peripheral also supports data presented by core write transactions.

The CRC peripheral implements a reduced table-lookup algorithm to compute the signature of the data. A programmable 32-bit CRC polynomial is used to automatically generate the lookup table (LUT) contents.

Additional CRC peripheral modes allow for initializing large memory sections with a constant value, or for verifying that sections of memory are equal to a constant value.

## CRC Features

The CRC peripheral supports a number of key features, including memory scan modes for memory verification, memory transfer modes for on-the-fly CRC calculations while transferring data from one memory to another, a programmable 32-bit CRC polynomial with automatic LUT generation, and data mirroring options.

The CRC module includes the following features.

- CRC checksum computation and comparison modes
- 32-bit programmable CRC polynomial with bit reverse option
- Automatic look up table (LUT) generation
- Data mirroring options for endian and reflected polynomial cases
- Automatic clear and preset of results
- Fault and error interrupt reporting
- DMA and MMR based operation

Since the CRC module is closely tied to memory-to-memory DMA (MDMA) channel pairs, the use cases include the following features.

- Memory scan with CRC compute or compare
- Memory transfer with CRC compute or compare
- Memory fill with 32-bit data patterns
- Memory verify
- MMR write access to FIFO of destination DMA
- MMR read access to FIFO of source DMA
- Profiting from advanced DMA features, like descriptor mode and bandwidth control/monitor

## CRC Functional Description

The CRC peripheral supports a number of modes of operation that allows for the initialization and verification of regions of memory. The peripheral supports efficient memory fill and verification operations on regions of memory with or against a constant value. These modes of operation do not require the CRC engine to calculate a signature. Other modes of operation allow for the CRC signature to be calculated and verified for a memory region and also allow for on the fly CRC calculation when performing memory-to-memory DMA transfers from one memory region to another.

In order to minimize the need for core accesses, the peripheral is interfaced to memory-to-memory DMA (MDMA) channels, allowing for flexible configuration in which data may be written to or read from the peripheral via DMA transactions, core transactions, or a combination of both. Two DMA channels are supported, to provide both a data input and data output. CRC0 is connected to the MDMA0 channel pair and CRC1 is connected to the MDMA1 channel pair.

**Figure 12-1:** Memory Flow

The following sections describe in further detail the functional operation of the CRC peripheral:

- [CRC Register List](#)
- [CRC Definitions](#)
- [CRC Block Diagram](#)
- [CRC Architectural Concepts](#)

The CRC peripheral supports a number of modes of operation that allow for the initialization and verification of regions of memory. The peripheral supports efficient memory fill and verification of memory

regions with a constant value in which the modes of operation do not require the need to enable the CRC engine to calculate a signature. Other modes of operation allow for the CRC signature to be calculated and verified for a memory region or also to allow for the signature to be calculated and verified on the fly while doing a memory-to-memory DMA operation from one memory region to another.

## CRC Register List

The cyclic redundancy check (CRC) unit includes the data comparison, polynomial operation, and look up table generation features needed for CRC operation. The CRC provides CRC protection as specified by the ASIL (Automobile Safety Integrity Level) requirements for the ADAS (Advanced Driver Assistance System) segment. This unit meets the requirements that the system software should be able to periodically check the correctness of the code/data available in the memory. A set of registers govern CRC operations. For more information on CRC functionality, see the CRC register descriptions.

**Table 12-1:** CRC Module Registers

| Name           | Description                     |
|----------------|---------------------------------|
| CRC_CTL        | Control Register                |
| CRC_DCNT       | Data Word Count Register        |
| CRC_DCNTRLD    | Data Word Count Reload Register |
| CRC_COMP       | Data Compare Register           |
| CRC_FILLVAL    | Fill Value Register             |
| CRC_DFIFO      | Data FIFO Register              |
| CRC_INEN       | Interrupt Enable Register       |
| CRC_INEN_SET   | Interrupt Enable Set Register   |
| CRC_INEN_CLR   | Interrupt Enable Clear Register |
| CRC_POLY       | Polynomial Register             |

## ADSP-BF60x CRC Interrupt List

**Table 12-2:** ADSP-BF60x CRC Interrupt List

| Description               | ID | DMA Channel | Sensitivity |
|---------------------------|----|-------------|-------------|
| CRC0 Datacount expiration | 88 |             | LEVEL       |
| CRC0 Error                | 89 |             | LEVEL       |
| CRC1 Datacount expiration | 92 |             | LEVEL       |
| CRC1 Error                | 93 |             | LEVEL       |

## CRC Definitions

To make the best use of the CRC, it is useful to understand the following terms.

### CRC

Acronym for Cyclic Redundancy Check. An error detection code that is capable of detecting changes within a block of data.

### CRC Polynomial

The 32-bit polynomial used by the CRC engine to generate the Look-Up-Table required for the CRC implementation

### LUT

Acronym for the Look-Up-Table. The Look-Up-Table is automatically generated from the supplied 32-bit CRC polynomial.

### DMA

Acronym for Direct Memory Access. Used to describe a data transfer that takes place via a DMA channel allowing data to be distributed around a system without intervention from the core.

### MDMA

Acronym for Memory-To-Memory DMA transfer that often requires the use of two DMA channels to transfer data from one memory region to another memory region. One DMA channel is configured as a source channel and the second as a destination channel. Acronym for the Look-Up-Table. The Look-Up-Table is automatically generated from the supplied 32-bit CRC polynomial.

## CRC Block Diagram

The figure shows the functional block diagram of the CRC peripheral.

**Figure 12-2:** CRC Block Diagram

## Peripheral DMA Bus

The CRC peripheral provides both an incoming and outgoing data path to the Peripheral DMA Bus. The MDMA source channel is interfaced to the incoming data path providing data to the CRC peripheral. For memory transfer and data fill modes, the MDMA destination channel is used to either output the data from the CRC FIFO or the data to be used for the fill operation.

## MMR Access Bus

The MMR access bus is used by the core to access all the memory-mapped registers of the peripheral for configuration, status and debug purposes. The core may also use the MMR access bus to feed data to the

CRC peripheral or read data from the FIFO of the CRC peripheral as an alternative to the operation being performed by the DMA channels.

Data received by MMR writes can transfer to destination DMA. Similarly, data received by source DMA can be output MMR interface. Optionally, intermediate results can be made available to MMR interface.

## Compare Logic

The compare logic takes the final CRC signature and compares this to the expected CRC signature, generating a CRC compare error if the signatures do not match. A compare error can flag a system fault.

## Mirror Block

The mirror block individually controls bit reversing of the polynomial, the computation results and the expected result. Endian and reflection of processed data can be controlled by bit mirroring, byte mirroring, word swapping and any combination of thereof.

## CRC Data FIFO

The CRC Data FIFO is a 32-bit-wide 4-entry FIFO. The FIFO is accessible to both the Peripheral DMA bus and the MMR Access bus. The FIFO status is accessible from the `CRC_STAT` register.

## CRC Engine

The CRC Engine is a 32-bit CRC engine that implements the Reduced Table Lookup scheme. The CRC engine provides support for a user-programmable 32-bit polynomial that is used to load the lookup table parameters required for the CRC calculation. The CRC engine is a 2-cycle implementation operating on 16 bits of data per cycle.

## DMA Request Generator

The DMA Request Generator is responsible for granting incoming DMA requests from the source DMA channel and issuing outgoing DMA requests to the destination DMA channel.

## CRC Architectural Concepts

The CRC peripheral includes a 32-bit CRC engine that implements the reduced table lookup scheme operating on 16 bits of data per cycle, resulting in a 2-cycle implementation for each 32 bits of data written to the peripheral. The upper 16 bits of the data are processed in the first cycle, followed by the lower 16 bits.

A 32-bit polynomial is required before calculation of the CRC signature can occur. The polynomial is used to generate the contents of an internal lookup table that is required by the reduced table lookup implementation. The lookup table that is automatically generated when the polynomial is written must be initialized prior to any operation that requires the use of the CRC engine.

The data presented to the CRC engine may be manipulated by the mirror block logic before being used in the calculation of the CRC signature. The data mirror operation is configurable to allow for bit reversing, byte reversing and 16-bit word swapping operations to be applied to the incoming data. For memory transfer compute and compare operations, the user may configure the peripheral to output the data in the same form in which it was received, or output the mirrored data in the same manner that it is presented to the CRC engine.

While the CRC peripheral is in operation, the status of the FIFO is continually updated and reflected in the `CRC_STAT` register. The FIFO status is required for core-based accesses to the CRC peripheral. The status indicates when the CRC peripheral is capable of receiving data, when data is available to be read from the FIFO and when the result of the `CRC_RESULT_CUR` register has been updated, indicating that the current CRC calculation has completed and the result is available.

## Lookup Table

The lookup table consists of a set of 16 32-bit registers that are automatically populated by hardware when a write access takes place to the `CRC_POLY` register. 16 clock cycles are required to generate all 16 look up table entries. The status of the lookup table generation process is reflected in `CRC_STAT.LUTDONE`, allowing for software to poll on the completion of the event or for generation of an interrupt.

**NOTE:** The lookup table must be populated before any operation requiring the use of the CRC peripheral can take place, even if the operation does not require the use of the CRC engine. The peripheral will not issue any data requests until the table generation process has completed. In addition, the `CRC_STAT.IBR` field that indicates the input buffer status as required for core-based transfers is only valid upon completion of the lookup table generation process.

## Data Mirroring

The data mirror block may be configured to manipulate the incoming data before the data is passed on to the CRC engine and, optionally, to the FIFO. This allows the peripheral to handle various forms of endianness and to function with reflected polynomials.

There are three configuration bits that control the data mirroring process: `CRC_CTL.BITMIRR`, `CRC_CTL.BYTMIRR` and `CRC_CTL.W16SWP`. The following table details how these options affect the incoming data and the output that is generated by the mirror block.

**Table 12-3:** Data Mirroring Options

| W16SWP | BYTMIRR | BITMIRR | Output Data                                           |
|--------|---------|---------|-------------------------------------------------------|
| 0      | 0       | 0       | Dout[31:0] = Din[31:0]                                |
| 0      | 0       | 1       | Dout[31:0] = Din[24:31],Din[16:23],Din[8:15],Din[0:7] |
| 0      | 1       | 0       | Dout[31:0] = Din[7:0],Din[15:8],Din[23:16],Din[31:24] |

**Table 12-3:** Data Mirroring Options (Continued)

| W16SWP | BYTMIRR | BITMIRR | Output Data                                            |
|--------|---------|---------|--------------------------------------------------------|
| 0      | 1       | 1       | Dout[31:0] = Din[0:7],Din[8:15],Din[16:23],Din[24:31]  |
| 1      | 0       | 0       | Dout[31:0] = Din[15:0], D[31:16]                       |
| 1      | 0       | 1       | Dout[31:0] = Din[8:15],Din[0:7], Din[24:31],Din[16:23] |
| 1      | 1       | 0       | Dout[31:0] = Din[23:16],Din[31:24], Din[7:0],Din[15:8] |
| 1      | 1       | 1       | Dout[31:0] = Din[16:23],Din[24:31], Din[0:7],Din[8:15] |

When the CRC is configured to operate in the memory transfer compute and compare mode, the bit-reversed output data may be written to the FIFO. This feature is controlled via the `CRC_CTL.FDSEL` field.

In addition to providing bit swapping and mirror options to the incoming data, the CRC peripheral also supports bit mirroring on the following registers:

- `CRC_RESULT_CUR` and `CRC_RESULT_FIN`, controlled via the `CRC_CTL.RSLTMIRR` field. When mirroring is enabled, the values to be written to these registers are fully bit-reversed before being written.
- `CRC_POLY`, controlled via the `CRC_CTL.POLYMIRR` field. When mirroring is enabled, the 32-bit polynomial is fully bit-reversed before being written to the register.
- `CRC_COMP`, controlled via the `CRC_CTL.COMPMIRR` field. When mirroring is enabled, the contents to be loaded to this register are fully bit-reversed before being written.

## FIFO Status and Data Requests

The CRC peripheral provides input and output buffer status indication via `CRC_STAT.IBR` and `CRC_START.OBR`, respectively. For core-based operations, software is required to monitor these status fields prior to writing to or reading from the CRC FIFO. No write to the CRC FIFO should occur while `CRC_STAT.IBR` indicates that the buffer is not ready to accept data. Similarly, the CRC FIFO should not be read until `CRC_START.OBR` indicates that data is available.

The memory scan modes of operation only require the monitoring of the input buffer status, whereas the memory transfer compute and compare mode is required to use both input and output buffer status. If at any point the current result of the CRC computation is required, then software must verify that the current operation has completed and that the intermediate result is ready, as indicated by `CRC_STAT.IRR`.

**NOTE:** The memory transfer fill mode of operation requires the use of a DMA channel. Core reads from the CRC FIFO for this mode of operations are not supported.

Memory transfer compute and compare mode makes use of burst transactions in order to make the most efficient use of the available resources. In this mode, when the FIFO is initially empty and the peripheral is enabled, the `CRC_STAT.IBR` bit indicates that the CRC is ready to accept data, and the peripheral gener-

ates data requests to the source DMA channel (if DMA is used). As long as the number of words remaining in the `CRC_DATCNT` register is greater than the FIFO depth, the peripheral issues data requests or accepts incoming data in bursts until the CRC FIFO becomes full.

Once full, `CRC_STAT.IBR` and `CRC_STAT.OBR` bits are updated accordingly, and then outgoing data requests are issued. Only when the FIFO is empty will the peripheral then can accept further incoming data, and `CRC_STAT.IBR` and `CRC_STAT.OBR` bits are updated once again.

Once `CRC_DATCNT` is decremented such that the number of words remaining to be processed is less than the number of words required to fill the FIFO, the burst mode of operation is disabled and incoming data is accepted as long as the FIFO is not full and outgoing data is available as long the FIFO is not empty. Therefore, there are no restrictions requiring the word count to be a multiple of the FIFO depth.

All other CRC modes of operation indicate that incoming data may be accepted as long as the FIFO is not full, and that outgoing data is available as long the FIFO is not empty.

The way in which data requests and the status bits are generated is additionally influenced by the `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` bit configurations described below.

- The `CRC_CTL.OBRSTALL` bit may be configured such that the CRC peripheral stalls as soon as there is output data available in the FIFO. This mode of operation should only be used in memory transfer compute and compare mode. This results in the processing of a single 32-bit word at a time. The peripheral does not request or accept incoming data until the current value being processed is read from the peripheral.
- The `CRC_CTL.IIRSTALL` bit may be configured so that the CRC peripheral stalls all further incoming data requests until the `CRC_RESULT_CUR` register is read after being updated. This mode of operation is only used for modes that result in CRC signature generation. It is not applicable to memory transfer data fill or memory scan data verify modes of operation.

## CRC Operating Modes

The following sections describe the various operating modes of the CRC interface.

### Data Transfer Modes

The CRC peripheral supports two main categories of operation involving data transfers:

- Memory Scan mode
- Memory Transfer mode

Memory scan modes are read-only operations that allow the contents of memory to be read into the peripheral and verified for correctness. There are two forms of memory scan mode:

- CRC Compute and Compare performs a CRC calculation on data presented to the peripheral and compares the CRC result with a pre-determined and pre-loaded result. An error is generated if the results differ.
- Data Verify compares each 32-bit data word presented to the CRC peripheral to a pre-loaded 32-bit value and generates an error if the data is found to be different.

Both of these modes of operation require, at the very most, a single DMA channel to read the data from memory into the peripheral. No data is forwarded to data output or destination DMA. Core-driven transfers may also be used for either of these modes of operation.

The memory transfer modes, involve memory write or memory read and write operations allowing for memory to be initialized or transferred from one region of memory to another. There are two forms of memory transfer mode:

- CRC Compute and Compare performs a full data transfer from one memory region to another memory region. A CRC signature is generated on the data presented to the peripheral and compared with a pre-determined and pre-loaded result. An error is generated if the results differ.
- Data Fill initializes a region of memory with a pre-loaded 32-bit constant value.

The CRC compute and compare mode of operation requires both incoming and outgoing data channels either in the form of DMA channels, core driven write/read operations to/from the FIFO or a combination of both. The data fill mode of operation requires only a memory write DMA destination channel, this mode does not support core driven operations.

## Memory Scan Compute and Compare

In this mode of operation the CRC Engine of the peripheral is enabled. The mode is configured through the `CRC_CTL.OPMODE` field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured via the `CRC_DCNT` register. The accumulated result of the CRC operation is contained in the `CRC_RESULT_CUR` register. Upon each 32-bit word being processed by the CRC engine the `CRC_DCNT` register is decremented and `CRC_RESULT_CUR` is updated.

Once `CRC_DCNT` decrements to zero, the contents of the `CRC_RESULT_CUR` register are copied to `CRC_RESULT_FIN` and `CRC_STAT.DCNTEXP` is updated accordingly. The `CRC_COMP` register is used to store the expected result of the CRC operation. Upon completion of the CRC calculation, `CRC_COMP` is compared with `CRC_RESULT_FIN` and `CRC_STAT.CMPERR` is updated to reflect the status of the compare operation. `CRC_STAT.CMPERR` is required to be cleared before the next CRC operation is performed.

The CRC peripheral also contains `CRC_DCNTRLD` register. This register is used to reload `CRC_DCNT` upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation may be configured via `CRC_CTL.AUTOCCLRZ` and `CRC_CTL.AUTOCCLR`. This provides a means to reset `CRC_RESULT_CUR` to `0x00000000`, `0xFFFFFFFF` or to leave the current register contents untouched for the next operation.

The peripheral may be configured to allow for the compare error and data expiration events to generate an interrupt.

## Memory Scan Data Verify

In this mode of operation the CRC engine of the peripheral is not required. The mode is enabled through the `CRC_CTL.OPMODE` field. Each 32-bit word of the data stream is compared with a constant value that is stored in the `CRC_COMP` register. The `CRC_DCNT` register contains the number of words that are to be compared. The `CRC_DCNT` register is decremented upon receiving a new 32-bit word from the data stream. If at any point the compare operation should fail the `CRC_STAT.CMPERR` bit updated accordingly and the contents of `CRC_DCNT` are captured in the `CRC_DCNTCAP` register. This may be used in order to identify the location in the data stream where the error occurred. The `CRC_STAT.CMPERR` field should be cleared in order to re-enable capturing of further errors.

Once `CRC_DCNT` decrements to zero, `CRC_STAT.DCNTEXP` is updated accordingly to signal the end of the operation. The peripheral may be configured to allow for the compare error and data expiration events to generate an interrupt.

## Memory Transfer Compute and Compare

In this mode of operation the CRC Engine of the peripheral is enabled. The mode is configured through the `CRC_CTL.OPMODE` field and the CRC engine performs a 32-bit CRC operation on the incoming data stream.

The length of the data stream is configured via the `CRC_DCNT` register. The accumulated result of the CRC operation is contained in the `CRC_RESULT_CUR` register. Upon each 32-bit word being processed by the CRC engine the `CRC_DCNT` register is decremented and `CRC_RESULT_CUR` is updated.

Once `CRC_DCNT` decrements to zero, the contents of the `CRC_RESULT_CUR` register are copied to `CRC_RESULT_FIN` and `CRC_STAT.DCNTEXP` is updated accordingly. The `CRC_COMP` register is used to store the expected result of the CRC operation. Upon completion of the CRC calculation, `CRC_COMP` is compared with `CRC_RESULT_FIN` and `CRC_STAT.CMPERR` is updated to reflect the status of the compare operation. `CRC_STAT.CMPERR` is required to be cleared before the next CRC operation is performed.

The CRC peripheral also contains `CRC_DCNTRLD` register. This register is used to reload `CRC_DCNT` upon completion of the CRC operation in preparation for the next transfer.

The initial seed of the CRC computation may be configured via `CRC_CTL.AUTOCCLRZ` and `CRC_CTL.AUTOCCLR`. This provides a means to reset `CRC_RESULT_CUR` to `0x00000000`, `0xFFFFFFFF` or to leave the current register contents untouched for the next operation.

The peripheral may be configured to allow for the compare error and data expiration events to generate an interrupt.

## Memory Transfer Data Fill Mode

In this mode of operation the CRC engine of the peripheral is not required. The mode is enabled through the `CRC_CTL.OPMODE` field. The `CRC_FILLVAL` register is written with a 32-bit value. This value is used to initialize a block memory via the Memory-to-Memory DMA Destination channel. When the CRC peripheral and the DMA destination channel are enabled, the contents of the `CRC_FILLVAL` register is written to the DMA channel to initialize the memory region. The `CRC_DCNT` register contains the number of words that are to be written.

Once `CRC_DCNT` decrements to zero, `CRC_STAT.DCNTEXP` is updated accordingly to signal the end of the operation. The peripheral may be configured to allow for the this data expiration event to generate an interrupt.

## CRC Event Control

The CRC peripheral has options to enable certain CRC status operations to generate an interrupt event to the System Event Controller. There, a CRC error can be qualified as a system fault.

## Interrupt Signals

The CRC peripheral is capable of generating two interrupts that may optionally be enabled within the System Event Controller. One is a CRC status interrupt and the other a CRC error interrupt.

The `CRC_STAT.CMPERR` status bit may be configured as an interrupt as is signalled via the CRC error interrupt signal. The `CRC_STAT.CMPERR` status field is set whenever a compare operation performed by the CRC peripheral fails. This may be as the result of a Memory scan data verify operation failing that compares the contents of a memory range with a constant 32-bit value, or it may be as a result of the CRC signature calculated for a memory region not matching the expected pre-programmed result for a memory scan or memory transfer compute compare operation.

The `CRC_STAT.DCNTEXP` status bit is set when the `CRC_DCNT` register has decremented to zero indicating that the CRC peripheral has now processed all the data that was requested for the current CRC operation. This signal may also be used to generate an interrupt. The interrupt is signalled on the CRC Status interrupt signal.

Both these status bits may be configured to generate an interrupt via the `CRC_INEN` register. `CRC_INEN` register also has bit set, `CRC_INEN_SET`, and bit clear `CRC_INEN_CLR` equivalent registers that may be used for the enabling and disabling of these interrupt sources.

The `CRC_STAT` register has two write one to clear (W1C) fields for clearing the two interrupt sources.

**NOTE:** Disabling the CRC peripheral via `CRC_CTL.BLKEN` does not result in the interrupt sources being cleared. The interrupt sources must be cleared via a W1C operation to `CRC_STAT`.

## CRC Programming Model

It is important to note the following restrictions when using the CRC peripheral in conjunction with the DMA channels:

1. When enabling the CRC peripheral and the DMA channels, the CRC peripheral should be enabled prior to enabling the DMA channels.
2. When disabling the CRC peripheral and the DMA channels, the DMA channels should be disabled prior to disabling the CRC peripheral.

## CRC Mode Configuration

Describes a number of tasks showing the various operation modes of the CRC peripheral.

- *Look-Up Table Generation*
- *Core Driven Memory Scan Compute Compare Mode*
- *DMA Driven Memory Scan Compute Compare Mode*
- *Core Driven Memory Scan Data Verify Mode*
- *DMA Driven Memory Scan Data Verify Mode*
- *Core Driven Memory Transfer Compute Compare Mode*
- *DMA Driven Memory Transfer Compute Compare Mode*
- *DMA Driven Memory Transfer Data Fill Mode*

## Look-Up Table Generation

Describes the steps required to initialize the CRC peripheral Look-Up Table.

1. Write the 32-bit CRC polynomial of choice to `CRC_POLY`

*ADDITIONAL INFORMATION:* This operation results in the CRC peripheral starting the Look-Up Table initialization process. `CRC_STAT.LUTDONE` is updated to reflect the operation is in progress.

2. Poll `CRC_STAT.LUTDONE` until the status bit indicates that the operation is completed.

*RESULT:* The CRC peripheral has completed initialization of all the Look-Up Table registers and is now ready for data operations. The `CRC_STAT.LUTDONE` field remains in the current state until `CRC_POLY` is written again, or the peripheral or processor are reset.

## Core Driven Memory Scan Compute Compare Mode

Performs CRC signature calculation and verification for a region of memory using core transactions. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured via `CRC_CTL` being disabled.

### *PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserved CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`.

#### 1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

#### 2. Initialize `CRC_DCNTRLD`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

#### 3. Initialize `CRC_RESULT_CUR`.

*ADDITIONAL INFORMATION:* This register may be initialized to provide an initial seed for the CRC operation that is about to take place.

#### 4. Initialize `CRC_COMP`.

*ADDITIONAL INFORMATION:* This register contains the pre-calculated final CRC signature result for the memory region that is used in the final compare operation.

#### 5. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

#### 6. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to Memory Scan Compute Compare Mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

- `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` options must be disabled for this task example.
- All mirroring and bit reversal options should also be configured.
- CRC auto clear options should also be configured.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

7. Write memory region data to the CRC peripheral.

a. While `CRC_STAT.IBR` indicates input buffer is ready, write `CRC_FIFO` with 32-bit data.

*ADDITIONAL INFORMATION:* This step is repeated until all required data has been written.

8. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

9. Poll `CRC_STAT.CMPERR` if the interrupt was disabled to check for a compare error.

*ADDITIONAL INFORMATION:* This step is only required if the compare error interrupt is not enabled.

10. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC Compute Compare operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

*RESULT:*

The integrity check of the memory via the expected CRC signature has completed and the final result is indicated via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits are cleared before performing a further CRC operation.

## DMA Driven Memory Scan Compute Compare Mode

Performs CRC signature calculation and verification for a region of memory using DMA transactions. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured via `CRC_CTL` being disabled.

*PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserviced CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize CRC\_DCNTRLD.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the CRC\_DCNT register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize CRC\_RESULT\_CUR.

*ADDITIONAL INFORMATION:* This register may be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize CRC\_COMP.

*ADDITIONAL INFORMATION:* This register contains the pre-calculated final CRC signature result for the memory region that is used in the final compare operation.

5. Initialize CRC\_INEN.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

6. Initialize CRC\_CTL with CRC\_CTL.OPMODE set to memory scan compute compare mode and CRC\_CTL.BLKEN configured to enable the CRC peripheral.

- CRC\_CTL.OBRSTALL and CRC\_CTL.IRRSTALL options must be disabled for this task example.
- All mirroring and bit reversal options should also be configured.
- CRC auto clear options should also be configured.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

7. Configure and enable the Memory-to-Memory Source DMA channel for memory read STOP mode.

*ADDITIONAL INFORMATION:* This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

8. Poll CRC\_STAT.DCNTEXP if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

9. Poll CRC\_STAT.CMPERR if the interrupt was disabled to check for a compare error.

*ADDITIONAL INFORMATION:* This step is only required if the compare error interrupt is not enabled.

10. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC Compute Compare operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation..

*STEP RESULT:*

*RESULT:*

The integrity check of the memory via the expected CRC signature has completed and the final result indicated is via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits are cleared before performing a further CRC operation. Any `W1C` status bits of the Memory-to-Memory Source DMA channel should also be cleared before the next CRC operation.

## Core Driven Memory Scan Data Verify Mode

Reads a region of memory using core transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

*PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserved CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`. The interrupt service routine for the compare error interrupt should read and store the contents of `CRC_DCNTCAP` to a buffer before clearing the compare error interrupt.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize `CRC_DCNTRLD`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize `CRC_COMP`.

*ADDITIONAL INFORMATION:* This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32-bit of data presented to the peripheral will be compared with this value.

4. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

5. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to Memory Scan Data Verify Mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

6. Write memory region data to the CRC peripheral.

- a. Poll `CRC_STAT.IBR` until input buffer is ready.
- b. Write `CRC_FIFO` with 32-bit data.

*ADDITIONAL INFORMATION:*

These two steps are repeated until the entire memory region has been written to the CRC peripheral.

7. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

8. Check if the buffer used to capture the `CRC_DCNTCAP` register upon a compare error has any new entries.

*ADDITIONAL INFORMATION:* The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC Memory Scan Verify operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

*STEP RESULT:*

*RESULT:*

The result of the integrity check of the memory with the 32-bit constant is indicated via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled. Each comparison error is traceable due to the logging of `CRC_DCNTCAP` from within the compare error interrupt handler.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits are cleared before performing a further CRC operation.

## DMA Driven Memory Scan Data Verify Mode

Reads a region of memory using DMA transactions and performs a compare operation on each 32-bit word against a single pre-loaded 32-bit constant. The compare error interrupt is enabled to capture and log the location of any compare errors.

*PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserved CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`. The interrupt service routine for the compare error interrupt should read and store the contents of `CRC_DCNTCAP` to a buffer before clearing the compare error interrupt.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize `CRC_DCNTRL`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize `CRC_COMP`.

*ADDITIONAL INFORMATION:* This register contains the 32-bit constant that the memory region is expected to be filled with. Each 32-bit of data presented to the peripheral will be compared with this value.

4. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

5. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to memory scan data verify mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

6. Configure and enable the memory-to-memory source DMA channel for memory read STOP mode.

*ADDITIONAL INFORMATION:* This step starts the data transfer from the memory region and writes the data to the CRC peripheral.

7. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

8. Check if the buffer used to capture the `CRC_DCNTCAP` register upon a compare error has any new entries.

*ADDITIONAL INFORMATION:* The values captures in the buffer provide a means to locate where in the memory region the failures occurred.

9. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC Memory Scan Verify operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

*STEP RESULT:*

*RESULT:*

The result of the integrity check of the memory with the 32-bit constant is indicated via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled. Each comparison error is traceable due to the logging of `CRC_DCNTCAP` from within the compare error interrupt handler.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits and DMA status bits are cleared before performing a further CRC operation.

## Core Driven Memory Transfer Compute Compare Mode

Performs CRC signature calculation and verification for a region of memory using core transactions while copying the contents to another memory region. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured via `CRC_CTL` being disabled.

### *PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserved CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize `CRC_DCNTRL`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize `CRC_RESULT_CUR`.

*ADDITIONAL INFORMATION:* This register may be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize `CRC_COMP`.

*ADDITIONAL INFORMATION:* This register contains the pre-calculated final CRC signature result for the memory region that is used in the final compare operation.

5. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

6. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to Memory Transfer Compute Compare Mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

- `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` options must be disabled for this task example.
- All mirroring and bit reversal options should also be configured.
- CRC auto clear options should also be configured.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

7. Write memory region data to the CRC peripheral and read it back to the new destination.
  - a. While `CRC_STAT.IBR` indicates input buffer is ready, write `CRC_FIFO` with 32-bit data.
  - b. While `CRC_STAT.OBR` indicates output buffer is ready, read `CRC_FIFO` and store data to new destination.

*ADDITIONAL INFORMATION:* These two steps are repeated until all required data has been processed through the CRC peripheral and copied to the new destination.

8. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if the counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

9. Poll `CRC_STAT.CMPERR` if the interrupt was disabled to check for a compare error.

*ADDITIONAL INFORMATION:* This step is only required if the compare error interrupt is not enabled.

10. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC compute and compare operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

#### *RESULT:*

The memory region has been copied to a new location and an integrity check of the memory via the expected CRC signature has also completed and the final result is indicated via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled.

#### *AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits are cleared before performing a further CRC operation.

## **DMA Driven Memory Transfer Compute Compare Mode**

Performs CRC signature calculation and verification for a region of memory using DMA transactions. The memory region is also copied to another memory region via the use of Memory-to-Memory DMA trans-

fers. The CRC peripheral is configured such that it operates in the burst mode of operation due to the stalling options configured via `CRC_CTL` being disabled.

*PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserviced CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize `CRC_DCNTRL`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize `CRC_RESULT_CUR`.

*ADDITIONAL INFORMATION:* This register may be initialized to provide an initial seed for the CRC operation that is about to take place.

4. Initialize `CRC_COMP`.

*ADDITIONAL INFORMATION:* This register contains the pre-calculated final CRC signature result for the memory region that is used in the final compare operation.

5. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

6. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to Memory Transfer Compute Compare Mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

- `CRC_CTL.OBRSTALL` and `CRC_CTL.IRRSTALL` options must be disabled for this task example.
- All mirroring and bit reversal options should also be configured.
- CRC auto clear options should also be configured.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

7. Configure and enable the Memory-to-Memory Source DMA channel for memory read STOP mode and destination DMA channel for memory write STOP mode.

*ADDITIONAL INFORMATION:* This step starts the data transfer from one memory region to another via the Memory-to-Memory DMA channels and the CRC peripheral.

8. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

9. Poll `CRC_STAT.CMPERR` if the interrupt was disabled to check for a compare error.

*ADDITIONAL INFORMATION:* This step is only required if the compare error interrupt is not enabled.

10. Write `CRC_STAT` to clear both `CRC_STAT.DCNTEXP` and `CRC_STAT.CMPERR`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of these status bits should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC compute and compare operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation. The memory region has also been copied to its new destination.

*RESULT:*

The integrity check of the memory via the expected CRC signature has completed and the final result is indicated via `CRC_STAT.CMPERR` and the corresponding interrupt if it were enabled. The memory region has also been copied to its final destination.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits are cleared before performing a further CRC operation. Any `W1C` status bits of the Memory-to-Memory Source and Destination DMA channels should also be cleared before the next CRC operation.

## DMA Driven Memory Transfer Data Fill Mode

Initializes a region of memory to a constant 32-bit value using DMA transactions.

### *PREREQUISITE:*

The task assumes that the polynomial has been loaded and the look-up table is fully initialized, there are no previously unserved CRC interrupts pending, and the CRC block is currently disabled as per `CRC_CTL.BLKEN`.

1. Initialize `CRC_DCNT`.

*ADDITIONAL INFORMATION:* The value loaded must represent the number of 32-bit words in the memory region for which the CRC signature is to be calculated and verified.

2. Initialize `CRC_DCNTRL`.

*ADDITIONAL INFORMATION:* This is the value that is used to reload the `CRC_DCNT` register upon completion of current CRC operation. If no further operation is required then this register may be initialized to zero.

3. Initialize `CRC_FILLVAL`.

*ADDITIONAL INFORMATION:* This register contains the 32-bit constant that is used to fill the memory region.

4. Initialize `CRC_INEN`.

*ADDITIONAL INFORMATION:* This register is used to enable the generation of the CRC interrupts for notification of compare errors and block completion. Configure these interrupts as required. If enabled ensure the corresponding interrupt handlers are also configured.

5. Initialize `CRC_CTL` with `CRC_CTL.OPMODE` set to Memory Transfer Fill Mode and `CRC_CTL.BLKEN` configured to enable the CRC peripheral.

*STEP RESULT:* The CRC peripheral is now enabled and ready for data to be written by the core or DMA channel.

6. Configure and enable the Memory-to-Memory Destination DMA channel for memory write STOP mode.

*ADDITIONAL INFORMATION:* This step starts the data transfer taking the constant 32-bit value from the CRC peripheral and writing the data to the DMA channel.

7. Poll `CRC_STAT.DCNTEXP` if the interrupt was disabled.

*ADDITIONAL INFORMATION:* This step is required only if counter expired interrupt is disabled. Polling is required to ensure all the data has been processed.

8. Write `CRC_STAT` to clear `CRC_STAT.DCNTEXP`.

*ADDITIONAL INFORMATION:* If interrupts were enabled then the clearing of this status bit should be performed within the interrupt handlers for the respective interrupts.

*STEP RESULT:* The CRC Memory Transfer Fill operation is now complete and the CRC peripheral is ready to be configured for the next CRC operation.

*RESULT:*

The memory region is now filled with the constant data and the CRC peripheral is ready to be configured for a new operation.

*AFTER COMPLETING THIS TASK:*

Ensure any `W1C` CRC status bits and DMA status bits are cleared before performing a further CRC operation.

## CRC Peripheral and DMA Channel List

**Table 12-4:** CRC DMA Channels

| DMA Channel | Peripheral    | FIFO Depth (Bytes) | Bandwidth Limit/Monitor Support |
|-------------|---------------|--------------------|---------------------------------|
| DMA21       | CRC0 Receive  | 128                | Yes                             |
| DMA22       | CRC0 Transmit | 64                 | Yes                             |
| DMA23       | CRC1 Receive  | 64                 | Yes                             |
| DMA24       | CRC1 Transmit | 64                 | Yes                             |

**Table 12-5:** CRC DMA Channels (Continued)

| DMA Channel | Memory Bus Width | Peripheral Bus Width | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------------|----------------------|-----------------------|------------------------|
| DMA21       | 32-bit           | 32-bit               | 8                     | 7                      |
| DMA22       | 32-bit           | 32-bit               | 8                     | 4                      |
| DMA23       | 32-bit           | 32-bit               | 8                     | 4                      |
| DMA24       | 32-bit           | 32-bit               | 8                     | 4                      |

## CRC Register Descriptions

Cyclic Redundancy Check Unit (CRC) contains the following registers.

**Table 12-6:** CRC Module Registers

| Name           | Description                     |
|----------------|---------------------------------|
| CRC_CTL        | Control Register                |
| CRC_DCNT       | Data Word Count Register        |
| CRC_DCNTRLD    | Data Word Count Reload Register |
| CRC_COMP       | Data Compare Register           |
| CRC_FILLVAL    | Fill Value Register             |
| CRC_DFIFO      | Data FIFO Register              |
| CRC_INEN       | Interrupt Enable Register       |
| CRC_INEN_SET   | Interrupt Enable Set Register   |
| CRC_INEN_CLR   | Interrupt Enable Clear Register |
| CRC_POLY       | Polynomial Register             |
| CRC_STAT       | Status Register                 |
| CRC_DCNTCAP    | Data Count Capture Register     |
| CRC_RESULT_FIN | CRC Final Result Register       |
| CRC_RESULT_CUR | CRC Current Result Register     |
| CRC_REVID      | Revision ID Register            |

### Control Register

The CRC\_CTL configures the operation modes and settings for the CRC.

CRC\_CTL: Control Register - R/W

Reset = 0x0000 0000

Figure 12-3: CRC\_CTL Register Diagram

Table 12-7: CRC\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22      | CMPMIRR  | COMPARE Register Mirroring.<br>The CRC_CTL.CMPMIRR enables data mirroring for the CRC_COMP compare register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for comparison with the CRC_RESULT_FIN register. |
|         |          | 0 Disable compare mirroring                                                                                                                                                                                                                                                    |
|         |          | 1 Enable compare mirroring                                                                                                                                                                                                                                                     |

**Table 12-7:** CRC\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 21      | POLYMIRR | Polynomial Register Mirroring.<br>The <code>CRC_CTL.POLYMIRR</code> enables data mirroring for the <code>CRC_POLY</code> polynomial register. When enabled, the 32-bit value in this register is fully bit mirrored (reversed). The bit-reversed value is used for CRC computations.                                                                                           |
|         |          | 0      Disable polynomial mirroring                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      Enable polynomial mirroring                                                                                                                                                                                                                                                                                                                                             |
| 20      | RSLTMIRR | Result Register Mirroring.<br>The <code>CRC_CTL.RSLTMIRR</code> enables data mirroring for the <code>CRC_RESULT_CUR</code> and <code>CRC_RESULT_FIN</code> result registers. When enabled, the 32-bit values in these registers are fully bit mirrored (reversed).                                                                                                             |
|         |          | 0      Disable result mirroring                                                                                                                                                                                                                                                                                                                                                |
|         |          | 1      Enable result mirroring                                                                                                                                                                                                                                                                                                                                                 |
| 19      | FDSEL    | FIFO Data Select.<br>The <code>CRC_CTL.FDSEL</code> selects whether the CRC writes modified or unmodified data to the FIFO in memory transfer mode. If enabled, the data written is affected by the state of the data mirroring selections ( <code>CRC_CTL.BITMIRR</code> , <code>CRC_CTL.BYTMIRR</code> , and <code>CRC_CTL.W16SWP</code> ) before being written to the FIFO. |
|         |          | 0      Write unmodified data to FIFO                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1      Write modified data to FIFO                                                                                                                                                                                                                                                                                                                                             |
| 18      | W16SWP   | Word16 Swapping.<br>The <code>CRC_CTL.W16SWP</code> enables the CRC's data mirror block to swap the upper and lower 16-bit words within the 32-bit input data, before further processing.                                                                                                                                                                                      |
|         |          | 0      Disable word16 swapping                                                                                                                                                                                                                                                                                                                                                 |

## Data Word Count Register

The `CRC_DCNT` holds the word count that is used for the CRC operation. On transfer of every 32-bit word, the CRC decrements by 1 the content of this register. When the count decrements to zero, this event triggers a CRC compare action, and `CRC_DCNT` is automatically loaded from the `CRC_DCNTRLD` for the next CRC operation. Note that the initial value programmed into `CRC_DCNT` may be different from what is programmed in the `CRC_DCNTRLD`.

**CRC\_DCNT: Data Word Count Register - R/W**

Reset = 0x0000 0000

**Figure 12-4:** CRC\_DCNT Register Diagram

**Table 12-8:** CRC\_DCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Data Word Count.        |

## Data Word Count Reload Register

The `CRC_DCNTRLD` holds the value that the CRC automatically loads into `CRC_DCNT` when the `CRC_DCNT` decrements to 0. At startup, the value programmed in `CRC_DCNT` and `CRC_DCNTRLD` could be different. So, for the first iteration, the CRC operation happens for the count initially programmed in the `CRC_DCNT` register. While for subsequent CRC operations, the count is taken from the `CRC_DCNTRLD` register.

CRC\_DCNTRLD: Data Word Count Reload Register - R/W

Reset = 0x0000 0000

Figure 12-5: CRC\_DCNTRLD Register Diagram

Table 12-9: CRC\_DCNTRLD Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Reload Value.           |

Data Compare Register

The CRC\_COMP contains the value corresponding to the expected CRC result or signature for the current data stream. At the end of the operation, the content of this register is used to compare against the result produced by the CRC operation. In data verify mode, each incoming data value is compared with the content of this register.

CRC\_COMP: Data Compare Register - R/W

Reset = 0x0000 0000

Figure 12-6: CRC\_COMP Register Diagram

**Table 12-10:** CRC\_COMP Register Fields

| Bit No. | Bit Name | Description/Enumeration    |
|---------|----------|----------------------------|
| 31:0    | VALUE    | Expected CRC Result Value. |

## Fill Value Register

The `CRC_FILLVAL` holds the value that the CRC uses for the memory fill operation. In data fill mode, the value programmed in this register is used for the memory fill operation.

**CRC\_FILLVAL: Fill Value Register - R/W**

Reset = 0x0000 0000

**Figure 12-7:** CRC\_FILLVAL Register Diagram**Table 12-11:** CRC\_FILLVAL Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Memory Fill Value.      |

## Data FIFO Register

In memory transfer mode (non-data fill mode), the data from the DMA or processor core buses is written into the `CRC_DFIFO` on each input data grant (DMA grant or core write). Data is read from this FIFO on each output data grant (DMA grant or core read). FIFO status information is available in the `CRC_STAT` register. Whenever, the FIFO has valid data, output data requests are generated.

Note that---in non-memory transfer mode and in data fill mode---the input data actually does not get written into this FIFO. So, this register should not be read in these modes.

CRC\_DFIFO: Data FIFO Register - R/W

Reset = 0x0000 0000

Figure 12-8: CRC\_DFIFO Register Diagram

Table 12-12: CRC\_DFIFO Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Data FIFO Value.        |

Interrupt Enable Register

The CRC\_INEN unmask (enables) or mask (disables) interrupt requests generated in the CRC from going to the processor core. Note that CRC interrupts are not disabled when the CRC is disabled (CRC\_CTL.BLKEN =0).

CRC\_INEN: Interrupt Enable Register - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration               |
|---------|----------|---------------------------------------|
| 1       | CMPERR   | Compare Error Interrupt Enable Clear. |
|         |          | 0 No Effect                           |
|         |          | 1 Clear Bit                           |

## Polynomial Register

The CRC\_POLY holds a 32-bit polynomial for CRC operations. Bit 31 corresponds to coefficient of  $x^{31}$  of the CRC polynomial, bit 30 corresponds to coefficient of  $x^{30}$ , and so on through to bit 0. Coefficient of  $x^{32}$  is assumed to be "1" for any polynomial that is selected. Based on the polynomial in CRC\_POLY, the CRC generates a look-up table (LUT), which is used to compute the CRC of the incoming data stream.

### CRC\_POLY: Polynomial Register - R/W

Reset = 0x0000 0000

**Figure 12-12:** CRC\_POLY Register Diagram**Table 12-16:** CRC\_POLY Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | CRC Polynomial Value.   |

## Status Register

The CRC\_STAT indicates status for CRC operations and interrupt generation.

CRC\_STAT: Status Register - R/WA

Reset = 0x0000 0000

| 1       | CMPERR   | Compare Error.<br>The CRC_STAT.CMPERR indicates that a CRC mismatch or data mismatch has been detected. This W1C bit is not automatically cleared when the CRC is disabled (CRC_CTL.BLKEN =0). When the CRC sets this bit on detecting a mismatch, the CRC generates the CRC_INEN.CMPERR interrupt. While this bit is set, the CRC_DCNTCAP is disabled from capturing the data count values. |
|         |          | 0 No Status                                                                                                                                                                                                                                                                                                                                                                                  |
|         |          | 1 Compare Error                                                                                                                                                                                                                                                                                                                                                                              |

## Data Count Capture Register

The CRC\_DCNTCAP captures the CRC\_DCNT value when a compare operation fails in data verify mode. This capture can be used to track the position of error in the data stream. Capture operation is enabled only if the CRC\_STAT.CMPERR indicates no compare error. After an error occurs and data count is captured, no further errors are logged until the CRC\_STAT.CMPERR bit is cleared. To obtain the position of error in the data stream, subtract the CRC\_DCNTCAP value from the initial CRC\_DCNT.

### CRC\_DCNTCAP: Data Count Capture Register - R/W

Reset = 0x0000 0000

**Figure 12-14:** CRC\_DCNTCAP Register Diagram

**Table 12-18:** CRC\_DCNTCAP Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 31:0    | VALUE    | Data Count Capture Value. |

## CRC Final Result Register

The CRC\_RESULT\_FIN holds the final CRC computed for a data stream. A data stream is a DMA of CRC\_DCNT number of words into the CRC. When CRC\_DCNT decrements to zero for each datastream, the CRC loads CRC\_RESULT\_FIN with the value from CRC\_RESULT\_CUR.

CRC\_RESULT\_FIN: CRC Final Result Register - R/W

Reset = 0x0000 0000

Figure 12-15: CRC\_RESULT\_FIN Register Diagram

Table 12-19: CRC\_RESULT\_FIN Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Computed CRC.           |

## CRC Current Result Register

The CRC\_RESULT\_CUR holds the current or intermediate CRC result and is updated when new data is written into the CRC. Each time the CRC\_DCNT expires, the CRC loads the value from this register into the CRC\_RESULT\_FIN. The CRC\_RESULT\_CUR may be set to auto clear to zero or auto clear to ones when CRC\_DCNT expires by configuring the CRC\_CTL.AUTOCLRZ and CRC\_CTL.AUTOCLR bits. Before starting a CRC operation, the CRC\_RESULT\_CUR should be programmed to the desired value. Note that this register can be read by the processor core at any time.

| 3:0     | REV      | Incremental Revision ID. |

# 13 Direct Memory Access (DMA)

The DMA channels are dispersed throughout the infrastructure and may be clustered together via system crossbars (SCB) so as to share a single interface with the main system crossbar.

The DMA channels can perform transfers between memory and a peripheral or between one memory and another memory. Two DMA channels are required for memory to memory DMA transfers (MDMA). One channel is the source channel, and the second, the destination channel.

All DMA channels can transport data to and from virtually all on-chip and off-chip memories.

DMA transfers on the processor can be descriptor-based or register-based. Register-based DMA allows the processor to directly program DMA controller registers to initiate a DMA transfer. On completion, the controller registers may be automatically updated with their original setup values for continuous transfer, if needed. Descriptor-based DMA transfers require a set of parameters stored within memory to initiate a DMA sequence. Descriptor-based transfers allow the chaining together of multiple DMA sequences. In Descriptor-based DMA operations, a DMA channel can be programmed to automatically set up and start another DMA transfer after the current sequence completes.

The DMA channel does not connect external memories and devices directly. Rather, data is passed through an external memory interface port. Any kind of device that is supported by the external memory interface can also be accessed by DMA operation. This is typically flash memory, SRAM, DDR SDRAM, FIFOs, or memory-mapped peripheral devices.

## DMA Channel Features

The processor uses Direct Memory Access (DMA) to transfer data within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure and interface with the SCB crossbar.

The following list provides DMA interface features.

- Supports integer byte strides including byte strides of 0 and negative byte strides
- Register based configuration
  - Core writes DMA configuration
  - Supports automatic reloading for continuous operation
- Flexible descriptor based configuration

- DMA descriptors are fetched from memory
  - Support for variable descriptor sizes
- Flexible flow control
  - Transitions between the various descriptor based modes and for DMA termination
- Orthogonal transfers
  - Support for three transfer dimensions
  - 1-D and 2-D transfers supported per descriptor set
  - 3-D support provided by chained descriptor sets
- Configurable memory and peripheral transfer word sizes
  - Memory interface supports 8, 16, 32, 64, 128 and 256 bit transfers
  - Peripheral interface supports for 8, 16, and 32-bit transfers
- Interrupt notification
  - Row or work unit completion
  - Error conditions
- Incoming and outgoing trigger support
  - Trigger generation for row or work unit completion
  - Work unit can wait for incoming trigger
- MMR Access Bus
  - Provides access to memory mapped registers for configuration, monitoring and debug
- SCB Crossbar Interface
  - Connects the DMA Channel to the System Crossbar
- Peripheral DMA Bus
  - Interfaces the DMA channel to a peripheral or another DMA channel
- Peripheral data request interrupt support
- Bandwidth monitoring and limiting

## **DMA Channel Functional Description**

This section provides a functional description of the DMA channel interface.

## DMA Register List

The DMA channel (DMA) supports data transfers within memory spaces or between a memory space and a peripheral. The processor can specify data transfer operations and return to normal processing while the fully integrated DMA channel carries out the data transfers independent of processor activity. The DMA channels are dispersed throughout the infrastructure, as DMAs. A set of registers govern DMA operations. For more information on DMA functionality, see the DMA register descriptions.

**Table 13-1:** DMA Module Registers

| Name           | Description                              |
|----------------|------------------------------------------|
| DMA_DSCPTR_NXT | Pointer to Next Initial Descriptor       |
| DMA_ADDRSTART  | Start Address of Current Buffer          |
| DMA_CFG        | Configuration Register                   |
| DMA_XCNT       | Inner Loop Count Start Value             |
| DMA_XMOD       | Inner Loop Address Increment             |
| DMA_YCNT       | Outer Loop Count Start Value (2D only)   |
| DMA_YMOD       | Outer Loop Address Increment (2D only)   |
| DMA_DSCPTR_CUR | Current Descriptor Pointer               |
| DMA_DSCPTR_PRV | Previous Initial Descriptor Pointer      |
| DMA_ADDR_CUR   | Current Address                          |
| DMA_STAT       | Status Register                          |
| DMA_XCNT_CUR   | Current Count(1D) or intra-row XCNT (2D) |
| DMA_YCNT_CUR   | Current Row Count (2D only)              |
| DMA_BWLCNT     | Bandwidth Limit Count                    |
| DMA_BWLCNT_CUR | Bandwidth Limit Count Current            |
| DMA_BWMCNT     | Bandwidth Monitor Count                  |
| DMA_BWMCNT_CUR | Bandwidth Monitor Count Current          |

## **DMA Definitions**

To make the best use of the DMA channel, it is useful to understand the following terms.

### **Descriptor**

An individual configuration fetched from memory that maps to a single register within a DMA channel.

### **Descriptor Fetch**

The action of retrieving descriptors from memory through memory read operations and loading then into the DMA channel registers upon their read return.

### **Descriptor Set**

A group of descriptors associated with a single work unit.

### **Disabled State**

The channel is disabled because the enable bit (EN) = 0 or as a result of an error.

### **DMAC**

An acronym used for a DMA cluster

### **DMA Channel**

A single DMA engine that has all the capabilities and registers as defined for a given processor. A DMA channel or engine is connected to a single peripheral.

### **DMA Cluster**

A grouping of multiple DMA channels with a shared SCB crossbar interface, controller and arbiter. Also known as a DMAC

### **Initial Descriptor**

The first descriptor in the descriptor set.

### **MDMA**

Memory-to-Memory DMA Data transfer. Two DMA channels are paired to perform a Memory Read from one address location and a Memory Write of that data to another address location.

### **Stop State**

A time where the channel is enabled but not currently programmed to perform a data transfer. Programming the flow to STOP causes the channel to enter Stop State at the end of the work unit.

### **User**

Any person, debug, emulator, software routine or action taken by the Core that accesses the MMR Registers of the DMA channel or peripherals, or sets up data and descriptors in memory.

### **Wait State**

If instructed to wait for a trigger, the channel enters this state once it has completed a work unit. The channel remains in this state until a trigger occurs. If a trigger came in before reaching the wait state, the channel will skip over the Wait State upon completion of the work unit.

### **Work Unit**

A single data transaction or series of data transactions performed based on the configuration of the DMA channel. In the case of autobuffer mode, a new work unit is defined at the time all current count registers are initialized to start values. Once all the current count registers count down to zero, the work unit has completed.

### **Work Unit Chain**

A single work unit or a series of work units separated by a stop or disabled state. The work units in the chain are programmed to another descriptor flow. The last work unit in the chain is programmed to a flow of STOP or AUTO. STOP stops the state at the end of that work unit. AUTO is required to be disabled by disabling the DMA channel. A work unit chain is also known as a descriptor chain.

## **DMA Channel Block Diagram**

The figure shows the functional blocks within the DMA interface.

**Figure 13-1: DMA Channel Block Diagram**

For more information on the interfaces shown in the block diagram, see:

- [DMA Channel Peripheral DMA Bus](#)
- [DMA Channel MMR Access Bus](#)
- [DMA Channel Event Control](#)
- [DMA Channel SCB Interface](#)
- [DMA Channel List for ADSP-BF60x](#)

## DMA Channel Architectural Concepts

The DMA channel provides a means to transfer data between memory spaces or between memory and a peripheral via a number of system interfaces. The DMA channel provides an efficient means of distributing data throughout the system freeing up the processor core for other operations. Each peripheral that supports DMA transfers has its own dedicated DMA channel or channels with its own register set that configures and controls the operating modes of the DMA transfers.

### DMA Channel SCB Interface

The SCB interface connects the DMA channel to the SCB crossbar allowing for transfers to and from the processors internal memory and other suitable system resources.

The DMA channel connects to the system interconnect through the SCB interface allowing the DMA channel to perform work unit data transfers with memories such as L1, internal L2 and external L3. In addition to work unit data transfers, the SCB interface is also used for the fetching of descriptor sets for all the descriptor based transfer modes.

The DMA channel is capable of supporting data bus widths of 16, 32, 64 or 128-bits. The data bus widths for a given DMA channel on particular processor may vary and are not configurable. The assigned bus widths can be determined by the user through reading the `DMA_STAT.MBWID` field.

The DMA channel operates at `SCLK` frequency as does the SCB interface. The SCB crossbar handles the internal arbitration of the transfer requests of all the masters interfaced to the SCB crossbar instance.

### SCB Interface Signals

**Table 13-2:** SCB Interface Signals

| Signal            | Width (bits) | Description                                                                                                 |
|-------------------|--------------|-------------------------------------------------------------------------------------------------------------|
| SCB_WRITE_DATA    | 16/32/64/128 | Data bus used for write operations. The width of the bus can be determined from <code>DMA_STAT.MBWID</code> |
| SCB_WRITE_ADDRESS | 32           | Write address bus. Provides the address of the first transfer in a burst transaction                        |
| SCB_READ_DATA     | 16/32/64/128 | Data bus used for read operations. The width of the bus can be determined from <code>DMA_STAT.MBWID</code>  |
| SCB_READ_ADDRESS  | 32           | Read address bus. Provides the address of the first transfer in a burst transaction                         |

## SCB Burst Transfers

The SCB interface supports burst transfers for memory read and write operations. The burst length is a function of the DMA channels configurable memory size for the work unit and the fixed bus width of the DMA channels SCB data bus. If the DMA channel is configured such that the memory transfer size is less than or equal to the DMA channels bus width then the burst length is always 1. If the configured memory size is greater than the SCB interface bus width then the burst length is sufficient to transfer a transaction as specified by the configured memory size.

**Table 13-3:** DMA Channel SCB Burst Lengths

| Configured Memory Size | Burst Length      |                   |                   |                    |
|------------------------|-------------------|-------------------|-------------------|--------------------|
|                        | <i>16-bit Bus</i> | <i>32-bit Bus</i> | <i>64-Bit Bus</i> | <i>128-bit Bus</i> |
| 1 Bytes                | 1                 | 1                 | 1                 | 1                  |
| 2 Bytes                | 1                 | 1                 | 1                 | 1                  |
| 4 Bytes                | 2                 | 1                 | 1                 | 1                  |
| 8 Bytes                | 4                 | 2                 | 1                 | 1                  |
| 16 Bytes               | 8                 | 4                 | 2                 | 1                  |
| 32 Bytes               | 16                | 8                 | 4                 | 2                  |

## Data Address Alignment

In order to prevent addressing errors and maximize bandwidth of the SCB interface to the DMA channel, data addresses must be aligned to be a multiple of the programmable memory size of the DMA channels configuration.

There are situations in which entire work units cannot be transferred at the maximum configurable memory size. In this case the entire work unit may be fulfilled by reducing the configured memory size at the expense of bus bandwidth. However, through the use of descriptor sets, the first descriptor set can be configured to transfer data until the larger memory size alignments are met. A second descriptor set with a larger memory size configuration may then be used to transfer a bulk of the data in the work unit. Finally a third descriptor set may be used with a smaller memory size in order to complete any final data transfers that may not meet the alignment requirements of the previous descriptor set configuration.

**Table 13-4:** DMA Channel Address Alignment Requirements

| Configured Memory Size | Address Restriction |
|------------------------|---------------------|
| 1 Byte                 | No restriction      |

**Table 13-4:** DMA Channel Address Alignment Requirements (Continued)

| Configured Memory Size | Address Restriction |
|------------------------|---------------------|
| 2 Bytes                | ADDR[0] == 0        |
| 4 Bytes                | ADDR[1:0] == 0      |
| 8 Bytes                | ADDR[2:0] == 0      |
| 16 Bytes               | ADDR[3:0] == 0      |
| 32 Bytes               | ADDR[4:0] == 0      |

### Descriptor Set Address Alignment

All descriptor set addresses and descriptors within a descriptor set must be aligned to a 32-bit address. The memory size of the DMA channels configuration is ignored for descriptor set fetches, which avoids the need to align descriptor sets based on the previous descriptor sets memory width configuration. For descriptor sets containing only a single descriptor the transfer takes place as a single 32-bit transfer. For descriptor sets containing multiple descriptors, each 32-bit descriptor is fetched individually and treated as multiple 32-bit transfers.

## DMA Channel Peripheral DMA Bus

The peripheral DMA bus connects the DMA channel to a peripheral or another DMA channel.

### Peripheral DMA Bus

The DMA channel connects to peripherals or other DMA channels via the Peripheral DMA bus. This is a dedicated point-to-point interface supporting data bus widths of 8, 16, 32 or 64 bits. The data bus widths for a given DMA channel on a particular processor may vary and are not configurable. The assigned bus width can be determined by the user through reading the `DMA_STAT.PBWID` field.

The DMA channel operates at SCLK frequency as does the peripheral DMA bus.

### Peripheral DMA Bus Signals

**Table 13-5:** Peripheral DMA Bus Signals

| Signal          | Width (bits) | Description                                                                                                 |
|-----------------|--------------|-------------------------------------------------------------------------------------------------------------|
| PDMA_WRITE_DATA | 8/16/32/64   | Data bus used for write operations. The width of the bus can be determined from <code>DMA_STAT.PBWID</code> |
| PDMA_READ_DATA  | 8/16/32/64   | Data bus used for read operations. The width of the bus can be determined from <code>DMA_STAT.PBWID</code>  |

**Table 13-5:** Peripheral DMA Bus Signals (Continued)

| Signal         | Width (bits) | Description                                                                                                                                                                                      |
|----------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PDMA_DMA_GRANT |              | Control signals to indicate that data is valid for DMA channel read operations (peripheral transmit) and that the DMA channel is ready to receive data for write operations (peripheral receive) |
| PDMA_CMD       | 3            | Used by the peripheral for issuing DMA channel control commands                                                                                                                                  |
| PDMA_CTRL      |              | The control signals used by the peripheral to send various commands to the DMA channel and control the direction of flow                                                                         |

**Table 13-6:** PDMA\_CMD Peripheral DMA Control Commands

| Command | Name                | Description                                                      |
|---------|---------------------|------------------------------------------------------------------|
| b#000   | NOP                 | No operation                                                     |
| b#001   | Restart             | Restarts the current work unit from the beginning                |
| b#010   | Finish              | Finishes the current work unit and starts the next               |
| b#011   | Interrupt           | Immediately sets the DMA completion interrupt in the DMA channel |
| b#100   | Request Data        | Typical DMA data request                                         |
| b#101   | Request Data Urgent | Urgent DMA data request                                          |
| b#110   | Reserved            | Reserved                                                         |
| b#111   | Reserved            | Reserved                                                         |

## DMA Channel Peripheral Control Commands

The Peripheral DMA bus of the DMA channel provides a means for peripherals on the processor to issue commands to the DMA channel to provide greater control over the DMA channel operation allowing for improved real-time performance and relieving control and interrupt demands on the core. Peripherals may send commands to the DMA controller over the 3-bit PERI\_CMD bus. The DMA control commands extend the set of operations available to the peripheral beyond the simple “request data” command used by peripherals in general. Refer to the appropriate peripheral chapter for a description on how that peripheral uses DMA control commands.

While these DMA control commands are not visible to or controlled by the user, their use by a peripheral has implications for the structure of the DMA transfers which that peripheral can support. It is important that application software be written to comply with certain restrictions regarding work units and descriptor chains so that the peripheral operates properly whenever it issues DMA control commands.

### **Idle Command**

This command is driven by the when the DMA channel and the peripheral are enabled and no data requests are required.

### **Restart Command**

This command causes the current work unit to interrupt processing and start again, using the addresses and count values from the DMA\_ADDRSTART, DMA\_XCNT and DMA\_YCNT registers. No interrupt is signalled when the work unit terminates.

If a channel programmed for transmit (memory read) receives a Restart command, the channel momentarily pauses while any pending memory reads initiated prior to the Restart command are completed. During this period of time, the channel does not grant DMA requests. Once all pending reads have been flushed from the channel's pipelines, the channel resets its counters and FIFO, and starts pre fetch reads from memory. DMA data requests from the peripheral are granted as soon as new pre fetched data is available in the DMA FIFO. In this case the peripheral can use the Restart command to reattempt a failed transmission of a work unit.

If a channel programmed for receive (memory write) receives a Restart command, the channel stops writing to memory, discards any data held in its DMA FIFO, and resets its counters and FIFO. As soon as this initialization is complete, the channel again grants DMA write requests from the peripheral. In this case the peripheral can use the Restart command to abort the transfer of received data into a work unit, and reuse the memory buffer for a later data transfer.

The Restart Control Command request is not granted/acknowledged. The request is always accepted by the DMA controller

### **Finish Command**

The Finish Command causes the current work unit to terminate processing and move on to the next work unit. An interrupt/trigger event is signalled as usual, (if enabled within the DMA\_CFG register). The peripheral can then use the Finish command to partition the DMA stream into work units on its own, perhaps as a result of parsing the data currently passing through its supported communication channel, without direct real-time control by the processor.

If a channel is programmed for transmit (memory read) operation and receives a Finish command, the channel momentarily pauses while any pending memory reads initiated prior to the Finish command are completed. During this period of time, the channel does not grant DMA requests. Once all pending reads have been flushed from the channel's pipelines, the channel signals an interrupt/trigger (if enabled), and begins fetching the next descriptor (if any). DMA data requests from the peripheral are granted as soon as new pre fetched data is available in the DMA FIFO.

If a channel programmed for receive (memory write) receives a Finish command, the channel stops granting new DMA requests while it drains its FIFO. Any DMA data received by the DMA channel prior to the finish Command is written to memory. When the FIFO reaches an empty state, the channel signals an interrupt/trigger (if enabled) and begins fetching the next descriptor (if any). Once the next descriptor has been fetched, the channel initializes its FIFO, and then resumes granting DMA requests from the peripheral.

The Finish command request is not granted/acknowledged. The request is always accepted by the DMA channel

## **Interrupt Command**

The Interrupt command causes the DMA channel to generate an interrupt. When programming the channel to support this command, the `DMA_CFG.INT` bit field must be configured to PIRQ mode so that the channel does not generate interrupts based on work unit state, but instead generates interrupts only when it receives the Interrupt command from the peripheral. Upon receiving an Interrupt command, the event is indicated in the `DMA_STAT.PIRQ` bit if all of the following conditions are satisfied.

- The DMA channel is enabled as per the `DMA_CFG.EN` bit.
- The DMA channel is in the stop state.
- The interrupt in `DMA_CFG.INT` is configured for PIRQ mode.

The peripheral only issues the Interrupt command in response to the Last Grant command being received from the DMA channel which indicates that the transfer is the last transfer in the work unit.

## **Request Data Command**

The Request Data command is a request for data transfers between the DMA channel and the peripheral. The request is held by the peripheral until granted/acknowledged by the DMA channel.

## **Request Data Urgent Command**

The Request Data Urgent command behaves identically to the Request Data command, except that while it is asserted the DMA channel performs its memory accesses with urgent priority. This includes both data and descriptor fetch memory accesses. A DMA management capable peripheral might use this control command if, for example, an internal FIFO is approaching a critical condition.

The request is held by the peripheral until granted/acknowledged by the DMA channel

## **DMA Channel Peripheral Control Command Restrictions**

The proper operation of the DMA channel FIFO leads to certain restrictions in the sequence of DMA Peripheral Control commands issued by a peripheral.

## Transmit Restart or Finish

No restart or finish control command may be issued by a peripheral to a channel configured for memory read unless all the following conditions are met:

- The peripheral has already performed at least one DMA transfer in the current work unit.
- The current work unit has  $(FIFO\_SIZE/DMA\_CFG.MSIZE) + 1$  memory transfers remaining.

The first item ensures that the work unit has started. The second item ensures that the work unit has not completed. The second item is sufficiently large that it is always at least five more than the maximum data count prior to any restart or finish command. This implies that any work unit which might be managed by restart or finish commands must have `DMA_XCNT_CUR` and `DMA_YCNT_CUR` register values representing at least five data items.

The second item can be satisfied by ensuring that the number of memory transfers described by the descriptor is  $(FIFO\_SIZE/DMA\_CFG.MSIZE) + 1$  larger than the maximum number of memory transfers expected.

## Receive Restart or Finish

No restart or finish control command may be issued by a peripheral to a channel configured for memory write unless either of the following conditions is met.

- The number of peripheral transfers completed is less than  $(DMA\_CFG.MSIZE/DMA\_CFG.PSIZE) \times$  (Transfers described by descriptor)

In addition to either of the above two conditions, one of the following two conditions must also be met.

- The previous work unit was terminated by a finish command AND the peripheral has done at least one transfer in the current work unit.
- The peripheral has done  $(FIFO\_SIZE/DMA\_CFG.PSIZE) + 1$  transfers in the current work unit.

The first set of conditions ensures that the descriptor is still active while the second set ensures that data from the previous descriptor has left the FIFO and that the current descriptor has started.

## Finish Only

The peripheral has completed exactly  $(DMA\_CFG.MSIZE/DMA\_CFG.PSIZE) \times$  (Transfers described by descriptor) and gives the Restart/Finish command immediately in the next cycle following the last data transfer.

## DMA Channel MMR Access Bus

Provides access to the DMA channels memory mapped registers.

## MMR Access Bus

The MMR access bus provides access to all the DMA channels memory mapped registers for DMA channel configuration, monitoring and debug. The interface has a fixed 32-bit data bus for read and write accesses.

## MMR Access Bus Signals

The following table provides descriptions of the MMR access bus signals.

**Table 13-7:** MMR Access Bus Signals

| Signal         | Width (bits) | Description                                                   |
|----------------|--------------|---------------------------------------------------------------|
| MMR_WRITE_DATA | 32           | Data bus used for write operations to the MMRs from the core. |
| MMR_READ_DATA  | 32           | Data bus used to return read data from the MMRs               |
| MMR_READ_ADDR  | 7            | Address that is used to select the MMR to access              |

## DMA Channel Operation Flow

The flow of operation of the DMA channel is described in the following topics:

- [DMA Channel Startup](#)
- [DMA Channel Refresh](#)
- [DMA Operating Modes](#)
- [DMA Channel Stop Mode](#)
- [DMA Channel Errors](#)

## DMA Channel Startup

In order to enable a DMA operation on a given channel, some or all of the DMA parameter registers must first be written directly. The minimum set of register required to be initialized is dependent upon the desired mode of operation.

## DMA Channel Minimum Enable Requirements

To start a DMA operation on a given channel, some or all of the DMA parameter registers must first be initialized corresponding to the DMA channels desired operating mode

- For descriptor array based flow modes.
  - At a minimum the DMA\_DSCPTR\_CUR register must be written prior to writing to the DMA\_CFG register, which is the special action required to start the DMA channel.

- For descriptor list based flow modes.
  - At a minimum the `DMA_DSCPTR_NXT` register must be written prior to writing to the `DMA_CFG` register, which is the special action required to start the DMA channel.
- For non descriptor based flow modes, the `DMA_STARTADDR`, `DMA_XCNT` and `DMA_XMOD` registers must be written prior to the `DMA_CFG` register.

Programs can write other registers that might remain static throughout the course of the DMA activity. The DMA operation begins once the `DMA_CFG` register is written.

**ATTENTION:** When the `DMA_CFG` register is written directly by software the DMA controller recognizes this as the special startup condition that occurs when starting DMA for the first time on this channel or after the DMA channel is stopped. It is possible for a DMA error condition to be flagged regardless of the `DMA_CFG.EN` bit setting.

## DMA Channel Startup Operation

When the `DMA_CFG` register is written directly by software, the DMA channel recognizes this as the special startup condition that occurs when starting DMA for the first time on this channel or after the channel has entered to the Stop state.

When the descriptor fetch is complete and the DMA channel is enabled, the `DMA_CFG` descriptor element that was read into the `DMA_CFG` register assumes control. Before this point, the direct write to the `DMA_CFG` register had control.

At startup the selected flow mode and the and descriptor size determine the course of the DMA initialization process. The `DMA_CFG.FLOW` field determines whether to load more current registers from descriptor sets in memory, while `DMA_CFG.NDSIZE` details how many descriptor elements to fetch before starting the DMA. DMA registers not included in the descriptor are not modified from their prior values

For descriptor list flow modes the `DMA_DESC_PTR_NXT` register is copied into the `DMA_DESC_PTR_CUR` register. Then, fetches of new descriptor elements from memory are performed, indexed by the `DMA_DESC_PTR_CUR` register, which is incremented after each fetch. After completion of the descriptor fetch, the `DMA_DESC_PTR_CUR` register points to the next 32-bit word in memory past the end of the descriptor.

If the descriptor fetch is for a descriptor array mode transfer then the `DMA_DESC_PTR_NXT` register is not copied into the `DMA_DESC_PTR_CUR` register. Instead the descriptor fetch indexing begins with the value in the `DMA_DESC_PTR_CUR` register.

If `DMA_CFG` is not part of the fetched descriptor set, then the previous value, (originally as written on startup) control the work unit operation. If the `DMA_CFG` register is part of the fetched descriptor set then the value programmed by the MMR access control only the loading of the first descriptor fetched from memory. The subsequent DMA work units are controlled by the configuration of `DMA_CFG` register of the fetched descriptor set.

Once the descriptor fetch is complete or if the flow was originally configured for one of the register based flow modes then the DMA operation begins. The DMA channel immediately fills its FIFO. For a memory

write operation the DMA channel begins accepting data from its peripheral. In the case of a memory read operation the DMA channel begins memory reads when the DMA channel is granted access to the SCB bus.

When the DMA channel performs its first data memory access, its address and count computations take their input operands from the start registers (DMA\_ADDRSTART, DMA\_XCNT and DMA\_YCNT if required), and writes results back to the current registers (DMA\_ADDR\_CUR, DMA\_XCNT\_CUR and DMA\_YCNT\_CUR). Note also that the current registers are not valid until the first memory access is performed, which may be some time after the channel is started by the write to the DMA\_CFG register. The current registers are loaded automatically from the appropriate descriptor elements, overwriting their previous contents, as follows:

- DMA\_ADDRSTART is copied to DMA\_ADDR\_CUR
- DMA\_XCNT is copied to DMA\_XCNT\_CUR
- DMA\_YCNT is copied to DMA\_YCNT\_CUR

## **DMA Channel Refresh**

Upon completion of a work unit, the DMA channel performs the following operations:

- Completes the transfer of all data between memory and the DMA channel.
- If the DMA channel is configured for a memory read operation with the DMA\_CFG.SYN bit enabled, then a synchronized transition takes place. The DMA channel transfers all data to the peripheral before continuing.
- If interrupts/triggers are enabled, then the signals are forwarded from the DMA channel and the DMA\_STAT register is updated to indicate the interrupt/trigger events.
- If the flow was set to Stop mode, the DMA operation stops by setting the DMA\_STAT.RUN bit field to indicate the channel is no longer running. Any remaining data in the DMA channel's FIFO is transferred to the peripheral.
- For descriptor array mode:
  - Loads a new descriptor from memory into the DMA registers by way of the contents of the DMA\_DESC\_PTR\_CUR register, while incrementing the DMA\_DESC\_PTR\_CUR register. The descriptor size is taken from the DMA\_CFG.NDSIZE value prior to the fetch.
- For descriptor list mode:
  - Copies the DMA\_DESC\_PTR\_NXT register into the DMA\_DESC\_PTR\_CUR register. Next, the DMA channel fetches the descriptor from the new contents of the DMA\_DESC\_PTR\_CUR register and places these contents into the DMA registers while incrementing the DMA\_DESC\_PTR\_CUR register.
- For descriptor on demand array mode:

- Checks to see if an incoming trigger event has been detected.

If a trigger event has been detected, then the DMA channel loads a new descriptor from memory into the DMA registers from the contents of the `DMA_DESC_PTR_CUR` register, while incrementing the `DMA_DESC_PTR_CUR` register. The descriptor size is taken from the `DMA_CFG.NDSIZE` value prior to the fetch.

If a trigger event was not detected then the DMA channel begins the next work unit by reloading the current registers as described below.

- For descriptor on demand list mode:

- Checks to see if an incoming trigger event has been detected.

If a trigger event was detected, then the DMA channel copies the `DMA_DESC_PTR_NXT` register into the `DMA_DESC_PTR_CUR` register. Next, the DMA channel fetches the descriptor memory from the new contents of the `DMA_DESC_PTR_CUR` register and places these contents into the DMA registers while incrementing the `DMA_DESC_PTR_CUR` register.

If a trigger event was not detected then the DMA channel begins the next work unit by reloading the current registers as described in the step below.

- If flow was configured for anything other than Stop mode then the DMA channel begins the next work unit by reloading the current registers (`DMA_ADDR_CUR`, `DMA_XCNT_CUR` and `DMA_YCNT_CUR`) from their descriptor registers (`DMA_ADDRSTART`, `DMA_XCNT` and `DMA_YCNT`).

## DMA Channel Work Unit Transitions

Transitions from one work unit to the next are controlled by `DMA_CFG.SYNC` bit for a given work unit. In general, continuous transitions have lower latency at the cost of restrictions on changes of data format or addressed memory space in the two work units. These latency gains and data restrictions arise from the way the DMA FIFO pipeline is handled while the next descriptor is fetched.

In continuous transitions where synchronization is disabled, the DMA FIFO pipeline continues to transfer data to and from the peripheral or destination memory during the descriptor fetch and/or when the DMA channel is paused between descriptor chains. On the other hand, synchronized transitions provide better real-time synchronization of interrupts and triggers with a given peripheral state. Synchronized transitions also provide greater flexibility in the data formats and memory spaces of the two work units, at the cost of higher latency in the transition. In synchronized transitions, the DMA FIFO pipeline is drained to the destination or flushed (received data discarded) between work units.

**NOTE:** Work unit transitions for MDMA streams are controlled by the `DMA_CFG.SYNC` bit of the MDMA source channel. The `DMA_CFG.SYNC` bit of the MDMA destination channel is reserved and must be set to disabled state. In transmit (memory read) channels, the `DMA_CFG.SYNC` bit of the last descriptor prior to the transition controls the transition behavior. In contrast, in receive channels, the `DMA_CFG.SYNC` bit of the first descriptor of the next descriptor chain controls the transition.

## DMA Channel Transmit and MDMA Source Transitions

In DMA transmit (memory read) and MDMA source channels, the `DMA_CFG.SYNC` bit controls the interrupt timing at the end of the work unit and the handling of the DMA FIFO between the current and next work unit.

If the `DMA_CFG.SYNC` bit is configured to disable synchronization, a continuous transition is selected. In a continuous transition, just after the last data item is read from memory, these four operations all start in parallel:

- The interrupt/trigger (if any) is signalled.
- The `DMA_STAT` register is updated to indicate DMA status is completed.
- The next descriptor begins to be fetched.
- The final data items are delivered from the DMA FIFO to the destination memory or peripheral.

This allows the DMA channel to provide data from the FIFO to the peripheral continuously during the descriptor fetch latency period.

When synchronization is disabled, the final interrupt/trigger (if enabled) occurs when the last data is read from memory. This event occurs at the earliest time that the output memory buffer may safely be modified without affecting the previous data transmission. There may be a number of data items still remaining in the FIFO and not yet at the peripheral. This number is dependent upon the FIFO depth of the DMA channel. Therefore, in this configuration, the DMA interrupt should not be used as the sole means of synchronizing the shutdown or re configuration of the peripheral following a transmission.

**NOTE:** If continuous transition is selected on a transmit (memory read) descriptor, the next descriptor is required to have the same peripheral transfer size (`DMA_CFG.PSIZE`), read/write direction, and source memory (internal versus external) as the current descriptor.

Disabling synchronization, to select continuous transition on a work unit that is configured for Stop flow mode with interrupt/trigger enabled, can result in the event service routine being executed while the final data is still draining from the FIFO to the peripheral. This is indicated by the DMA channels `DMA_STAT.RUN` bits—if the channel is still running then the FIFO is not yet empty. Do not start a new work unit with different peripheral transfer size or direction while the channel is still running. Further, if the channel is disabled via the `DMA_CFG.EN` bit, the data in the FIFO is lost.

A synchronized transition allows the DMA FIFO to first be drained to the destination memory or peripheral before any interrupt is signalled, and before any subsequent descriptor or data is fetched. This incurs greater latency, but provides direct synchronization between the DMA interrupt and the state of the data at the peripheral.

For example, if synchronization is enabled and interrupts are enabled on the last descriptor in a work unit, the interrupt occurs when the final data is transferred to the peripheral. This allows the service routine to properly switch to non-DMA transmit operation. When the interrupt service routine is invoked, the DMA channel FIFO will be empty and the DMA channel will not still be running as indicated by the `DMA_STAT.RUN` bits.

A synchronized transition also allows greater flexibility in the format of the DMA descriptor chain. When enabled, the next descriptor may have any `DMA_CFG.PSIZE` configuration or read/write direction supported by the peripheral and may come from either memory space (internal as opposed to external). This can be useful in managing MDMA work unit queues, since it is no longer necessary to interrupt the queue between dissimilar work units.

## **DMA Channel Work Unit Receive and MDMA Destination Transitions**

In DMA receive (memory write) channels, the `DMA_CFG.SYNC` bit controls the handling of the DMA FIFO between descriptor chains (not individual descriptor sets), when the DMA channel is paused. The DMA channel pauses after descriptor sets configured with Stop flow mode complete, and the channel may be restarted (for example, after an interrupt) by writing the channel's `DMA_CFG` register with a value that enables the DMA channel. If the synchronization is disabled in the new work unit's `DMA_CFG` value, a continuous transition is selected. In this mode, any data items received into the DMA FIFO while the channel was paused are retained, and they are the first items written to memory in the new work unit. This mode of operation provides lower latency at work unit transitions and ensures that no data items are dropped during a DMA pause, at the cost of certain restrictions on the DMA descriptors.

**NOTE:** If the `DMA_CFG.SYNC` bit is configured to disable synchronization on the first descriptor of a descriptor chain after a DMA pause, the `DMA_CFG.PSIZE` field of the new chain must not change from the configuration of the previous descriptor chain that was active before the pause, unless the DMA channel is reset between chains by disabling and then re-enabling the DMA channel.

A synchronized transition is selected if the `DMA_CFG.SYNC` field is configured to enable synchronization. In this mode, only the data received from the peripheral by the DMA channel after the write to the `DMA_CFG` register is delivered to memory. Any prior data items transferred from the peripheral to the DMA FIFO before this register write are discarded. This provides direct synchronization between the data stream received from the peripheral and the timing of the channel restart (when the `DMA_CFG` register is written).

For receive DMA operations, the synchronization has no effect in transitions between work units in the same descriptor chain (that is, when the previous descriptor's flow mode was not STOP, so that DMA channel did not pause).

If a descriptor chain begins with synchronization enabled, there is no restriction on `DMA_CFG.PSIZE` of the new chain in comparison to the previous chain.

**NOTE:** The peripheral transfer size (`DMA_CFG.PSIZE`) must not change between one descriptor and the next in any DMA receive (memory write) channel within a single descriptor chain, regardless of the `SYNC` bit setting. In other words, all memory write descriptor sets in a descriptor chain must have the same `DMA_CFG.PSIZE` value. For any DMA receive (memory write) channel, there is no restriction on changes of peripheral transfer size (internal versus external) between descriptors or descriptor chains.

## **DMA Channel Transfer Termination and Shutdown**

This section describes channel transfer termination and shutdown in stop flow mode and in autobuffer flow mode.

## Stop Flow Mode

In Stop flow mode, the DMA channel stops automatically after the work unit is complete. If a list or array of descriptors is used to control DMA transfers, and if every descriptor contains a `DMA_CFG` descriptor element, then the final `DMA_CFG` descriptor element should have the flow configured to Stop mode setting to gracefully stop the channel. Upon completion the DMA channel remains in the Stop state. This state should not be confused with the disabled state which occurs either due to a DMA error or by configuring `DMA_CFG.EN` so as to disable the DMA channel.

Disabling the DMA channel via a write to the `DMA_CFG.EN` bit is intended to shut down the DMA channel and enter the disabled state. All memory and peripheral data transfers cease and only peripheral interrupts are passed through the DMA channels interrupt signals. However, the DMA channel maintains the `DMA_STAT.RUN` bits. Therefore, in the case of a memory write operation, the outstanding memory transaction counter keeps track of returning memory write acknowledgements and updates as required.

In the case of memory read operations, the outstanding memory transaction counter also keeps track of returning memory reads. However, the memory reads are not written into the FIFO. The counter is updated to reflect the completion of the transaction, but the data is ignored. The `DMA_STAT.RUN` bits remain in the “Waiting for Write ACK/FIFO Drain to Peripheral” state and do not change to “Stop/Idle State” until all outstanding transactions have returned.

When the DMA channel is enabled again via the `DMA_CFG.EN` bit, a full reset is performed and all counters are cleared. If an outstanding memory transaction returns an acknowledgement or read data after this event, then a memory transaction error has occurred and an error is generated. Programs must be sure that all outstanding memory transactions have been completed before re configuring the DMA channel. One method programs may use is to poll the `DMA_STAT.RUN` bits to return to the “Stop/Idle State” before proceeding.

## Autobuffer Flow Mode

In the case of Autobuffer flow modes, the only way to cease operations is to disable the DMA channel via the `DMA_CFG.EN` bit. Therefore, one method of changing to a new work unit would be to disable the DMA channel, set up all the registers (and descriptors in memory, if used) except for `DMA_CFG`, then poll `DMA_STAT.RUN` to wait for the status to reflect “Stop/Idle State”, and finally write `DMA_CFG` to the new configuration to begin the next work unit.

In autobuffer flow mode, or if a list or array of descriptor sets without `DMA_CFG` descriptors, then the DMA transfer process must be terminated by an MMR write to the `DMA_CFG` register with a value whose `DMA_CFG.EN` bit is configured to disable the DMA channel.

**CAUTION:** Interrupt logic based on work unit transitions are disabled when the DMA channel is disabled. Programmers should be aware of their environment and current actions so that additional interrupts are not required from the DMA channel.

**CAUTION:** The DMA channel completes any transactions that have begun and avoids generating bus errors if disabled through `DMA_CFG.EN` in the middle of a transaction. However, the action of re-enabling the DMA is considered a hard reset for all internal DMA channel components.

Therefore, programmers must pay special attention to that particular action in order to avoid unexpected results.

## **DMA Channel Errors**

When an error occurs, the DMA channel maintains all the state and register values which allows programs to diagnose error causes more thoroughly. The greatest benefit to the programmer is to know exactly what operational state the DMA channel was in at the exact moment the error occurred.

It is the responsibility of the programmer to take special care to ensure the root cause of the error is addressed, whether the problem originated in the DMA channel or not. If not properly resolved, the error could result in an additional error shortly after operations resume. The problem may have caused other errors elsewhere in the DMA channel or associated modules and circuitry, therefore care must be taken to address those potential problems also. Finally, the programmer must ensure that all outstanding memory reads and writes are complete, or cleared, before resuming DMA channel operation.

Once all issues have been addressed and all side effects of any error are neutralized, the programmer may clear the `DMA_STAT.ERR` status field and restart the DMA channel by disabling then re-enabling the DMA channel through the `DMA_CFG.EN` bit.

## **Status and Debug**

DMA channel error conditions can cause the DMA process to end abnormally. DMA error detection is provided as a tool for system development and debug, as a way to detect DMA related programming errors. When the DMA channel detects an error, the channel is immediately stopped and any memory read transactions that are returned are discarded. The DMA channels `DMA_STAT.RUN` field is set to indicate idle state, once all outstanding memory transactions are acknowledged. In addition, an error interrupt is asserted and the `DMA_STAT.IRQERR` is updated to reflect this. Also the error cause of the first detected error is updated in the `DMA_STAT.ERRC` field. Unless the error occurs at the exact moment that register values are being modified, the registers will contain their values.

It is possible for error interrupt signals to be combined. Combined error signals requires that the `DMA_STAT` register of each DMA channel associated with a combined error interrupt be read to determine the DMA channel responsible for the generation of the interrupt.

The DMA channel error interrupt handler is required to perform the following actions:

- Read each DMA channel's `DMA_STAT` register to look for a channel with the `DMA_STAT.IRQERR` set to indicate an error.
- Read the DMA channel's `DMA_STAT.ERRC` field to determine the cause of the error.
- Clear the problem with the DMA channel, for example fix the register values.
- Clear the error in the DMA channel via a write 1 to clear operation to the `DMA_STAT.IRQERR` bit.

If any error other than a bandwidth monitor error is already flagged and is not cleared, no other error is reported. If a bandwidth monitor error was reported and not cleared, any newly detected error would be in the updated `DMA_STAT.ERRC` field.

## DMA\_CFG Register Errors

These errors are only flagged when the DMA channel is enabled via the DMA\_CFG.EN bit.

- Reserved setting was used
- DMA\_CFG.TWAIT enabled in Descriptor On Demand Flow mode
- Illegal DMA\_CFG.NDSIZE
- Illegal DMA\_CFG.MSIZE
- DMA\_CFG.MSIZE exceeds the DMA channel's FIFO size
- Illegal DMA\_CFG.PSIZE
- DMA\_CFG.PSIZE exceeds the FIFO size
- DMA\_CFG.PSIZE exceeds the bus width
- Memory Read (Transmit operation), cannot change to receive unless properly synced in the previous work unit, or if first work unit in a new chain
- Memory Read (Transmit operation), cannot change DMA\_CFG.PSIZE unless properly synced in previous work unit, or if first work unit in a new chain
- Memory Write (Receive operation), cannot change to transmit during a descriptor chain. Can only change from receive to transmit if new transmit is synced and first work unit
- Memory Write (Receive operation), cannot change DMA\_CFG.PSIZE unless first work unit with DMA\_CFG.SYNC enabled

## Illegal Register Write During Run

Write to writable registers when the DMA channel is enabled and running are blocked and generate an error. The DMA\_STAT, DMA\_BWLCNT and DMA\_BWMCNT registers are exempt from this behavior.

## Address Alignment Error

An address alignment error is generated when a descriptor address is not aligned to a 32-bit boundary or a transfer address is not aligned for the current DMA\_CFG.MSIZE configuration.

## Memory Access Error

A memory access error is generated when an attempt was made to access an address not populated, defined as cache, or there was a security violation. This error is triggered by an error returned from the memory.

## Trigger Overrun Error

A trigger overrun error is generated when a new trigger input occurred while an outstanding trigger is waiting. this error is only generated if DMA\_CFG.TOVEN is enabled.

## Bandwidth Monitor Error

This error is generated when the bandwidth monitor count expired. this is not a fatal error and the DMA channel will continue its operation.

## Control Interface Error

Control interface errors are reported as bus errors to the bus master. This can be as a result of:

- An address error
- Write to a read-only register

## DMA Channel Memory DMA

A Memory DMA (MDMA) channel provides a means of doing memory-to-memory DMA transfers among the various memory spaces that have DMA support.

Memory DMA (MDMA) channels are implemented by interfacing two DMA channels via the Peripheral DMA Bus Interface. One DMA channel is used for memory read operations and the second is used for memory writes. Depending on the processor, a memory DMA channel may have an additional peripheral, such as a CRC peripheral, inserted into the peripheral DMA bus that may optionally be enabled.

MDMA channel configurations that do not involve an additional peripheral impose no restrictions on which of the DMA channels is to be used for the read operation and which is to be used for the write operation so long as both are not configured for the same transfer direction. For MDMA channel configurations that enable a peripheral between the read and write channels, restrictions may be imposed on which channel may be used for a given transfer direction.

**Figure 13-2:** MDMA Channel Dedicated Pair

**Figure 13-3: MDMA Channel Pair with Peripheral**

A memory-to-memory transfer always requires the source and destination channels to be enabled. Because the channels are interfaced through the peripheral DMA bus, and because the channel may have an additional peripheral inserted into the peripheral DMA bus, programs must ensure that the `DMA_CFG.PSIZE` of both the source and destination channels are set to the same values.

The memory DMA channels support the full range of `DMA_CFG.MSIZE` options for the DMA transfers to and from the memories.

As the MDMA channel consists of two DMA channels, the entire MDMA channel has two sets of FIFOs, one in the read channel and one in the write channel. This allows for more efficient bursting of both read and write transactions in order to make use of the available bandwidth. While the `DMA_CFG.PSIZE` configuration must be identical for both source and destination DMA channels, this restriction is not imposed for the `DMA_CFG.MSIZE` configuration.

The independent source and destination DMA channels also have their own dedicated interrupt and trigger events, and while it is normal practice to only have event generation performed at destination DMA completion, programs are not restricted to this means of interrupt generation.

Configuration of an MDMA transfer is done in a similar manner to peripheral DMA transfers with the exception of writing two DMA channel registers instead of one.

## MDMA Triggering

To control the pace of data transfers, triggers may be used on either the memory read or the memory write channel pair used in an MDMA operation. Enabling `DMA_CFG.TWAIT` in the memory read channel will prevent both channels from transferring data before the system is ready. However, only configuring the memory write channel to wait for a trigger will allow for data to be fetched from the memory in anticipation of the memory write operation.

## DMA Operating Modes

The DMA channel supports a number of different flow modes that determines how the DMA channel progresses from one work unit to the next.

The flow mode of a DMA channel is not a global setting. A DMA descriptor set may include the descriptor responsible for configuring the flow of the work unit and there is no restriction that the flow must be configured the same for the entire descriptor chain. If the descriptor chain is not endless then the last descriptor set would configure the flow to stop mode resulting in termination of the descriptor chain after work unit completion. Another example for mixing flow modes would be to create an endless descriptor array. The last descriptor set in the array would be configured for list mode and the next descriptor pointer of this descriptor set would point to the first descriptor in the array.

## DMA Channel Register Based Flow Modes

Register-based DMA operations require configuration by directly writing to the DMA channels Memory Mapped Registers registers.

Register-based DMA is the traditional method of DMA operation. Software writes all the DMA channels configuration into the memory-mapped registers. This includes information such as the source or destination address and length of the data to be transferred and then starts the DMA channel operation. The DMA channel supports the following register-based flow modes:

- *DMA Channel Stop Mode*
- *Autobuffer Mode*

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor. The supported descriptor set sizes can differ between the various descriptor based flow modes. In addition to the descriptor set size being configurable, descriptor based DMA also allows for the flow mode of the next descriptor set to be altered allowing for the transition from descriptor array mode to descriptor list mode in addition to configuring the flow to stop or even autobuffer mode.

## DMA Channel Stop Mode

In Stop mode, the DMA operation is executed only once. If started, the DMA channel transfers the desired number of data words and stops itself again when finished. If the DMA channel is no longer used, software configures the enable bit to disable a paused channel. Interrupts and triggers may also be generated for each row/work unit completion depending upon desired configuration.

## Autobuffer Mode

In autobuffer mode, the DMA operates repeatedly in a circular manner. If all data words have been transferred, the address pointer (`DMA_ADDR_CUR`) is reloaded automatically with the `DMA_ADDRSTART` value. An interrupt may also be generated.

Autobuffer mode is enabled via the `DMA_CFG.FLOW` field. The `DMA_CFG.NDSIZE` field must be configured such that the next descriptor size is zero.

## DMA Channel Descriptor Based Flow Modes

Descriptor-based DMA operations fetch descriptor sets from memory allowing for autonomous loading of work units upon another work units.

Software is not required to set up the DMA sequences directly by writing into the DMA controller registers. Rather, software keeps DMA descriptor sets in memory. On demand the DMA controller autonomously loads the descriptor set from memory to the affected DMA controller registers. The descriptor sets can be fetched from any memory space that supports DMA read operations. The descriptor set describes the next operation to be performed by the DMA controller. The descriptor set may include information such as the DMA configuration word as well as data source/destination address, transfer count, and address modify values.

A descriptor set describes a single work unit, however some values from one descriptor set may be reused in the following work unit if they are not overwritten in the subsequent descriptor set fetches and the work unit requires the use of this descriptor.

The DMA channel supports the following flow modes with descriptor based operations:

- *DMA Channel Descriptor Array Mode*
- *DMA Channel Descriptor List Mode*
- *DMA Channel Descriptor On Demand Array Mode*
- *DMA Channel Descriptor On Demand List Mode*

The DMA channel supports variable descriptor set sizes within the configuration. The size of a descriptor set can contain as little as a single descriptor. The supported descriptor set sizes can differ between the various descriptor based flow modes. In addition to the descriptor set size being configurable, descriptor based DMA also allows for the flow mode of the next descriptor set to be altered. This allows programs to

transition from one descriptor based mode to another descriptor based mode in addition to a transition to any of the register-based flow modes.

## DMA Channel Descriptor Array Mode

When configured in this mode, the descriptor sets do not contain further descriptor pointers. The initial descriptor pointer value is written by software and points to an array of descriptors. The individual descriptors are assumed to reside next to each other and, therefore, their address is known.

### Descriptor Sets

The *Parameter Registers and Descriptor Offsets* table illustrates how a descriptor set must be structured in memory. Note that descriptor sets must reside in a contiguous block of memory in the format shown in the table. That is to say that the first descriptor of the next descriptor set must be located in the memory location immediately following the last descriptor of the current descriptor set. The values have the same order as the corresponding MMR offset addresses.

**Table 13-8:** Parameter Registers and Descriptor Offsets

| Descriptor Offset | Parameter Register |
|-------------------|--------------------|
| 0x00              | DMA_ADDRSTART      |
| 0x04              | DMA_CFG            |
| 0x08              | DMA_XCNT           |
| 0x0C              | DMA_XMOD           |
| 0x10              | DMA_YCNT           |
| 0x14              | DMA_YMOD           |

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. All of the current registers are reloaded between the descriptor set fetch and the start of the DMA operation for the work unit.

### Minimum Startup Requirements

At a minimum the DMA\_DSCPTR\_CUR register must be written prior to writing to the DMA\_CFG register, which is the special action required to start the DMA channel.

## DMA Channel Descriptor List Mode

In this flow mode, multiple descriptors form a chained list in which each descriptor set contains a pointer to the next descriptor set, allowing greater flexibility in memory layout options. When the descriptor set is fetched, this pointer value is loaded into the DMA channels next descriptor pointer register.

### Descriptor Sets

The [Descriptor List Mode Parameter and Descriptor Offsets](#) illustrates how a descriptor set must be structured in memory. Note that while the descriptor sets can be dispersed throughout memory and reside in different memory blocks, each descriptor of the descriptor set must reside in a contiguous section of memory in the format shown in the table. The values have the same order as the corresponding MMR offset addresses.

**Table 13-9:** Descriptor List Mode Parameter and Descriptor Offsets

| Descriptor Offset | Parameter Register |
|-------------------|--------------------|
| 0x00              | DMA_DSCPTR_NXT     |
| 0x04              | DMA_ADDRSTART      |
| 0x08              | DMA_CFG            |
| 0x0C              | DMA_XCNT           |
| 0x10              | DMA_XMOD           |
| 0x14              | DMA_YCNT           |
| 0x18              | DMA_YMOD           |

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. All of the register's current values are reloaded between the descriptor set fetch and the start of the DMA operation for the work unit.

### Minimum Startup Requirements

At a minimum the DMA\_DSCPTR\_NXT register must be written prior to write to the DMA\_CFG register which is the special action required to start the DMA channel.

## DMA Channel Descriptor On Demand Array Mode

When configured in this mode, the descriptor sets do not contain further descriptor pointers. The initial descriptor pointer value is written by software and points to an array of descriptors. The individual descriptors are assumed to reside next to each other and, therefore, their address is known.

At the end of the work unit, if the DMA channel has not detected an incoming trigger event, the current work unit is repeated. If the DMA channel receives an incoming trigger before completion of the work unit then a new descriptor set is fetched.

## Descriptor Sets

The *Parameter Registers and Descriptor Offsets* table illustrates how a descriptor set must be structured in memory. Note that descriptor sets must reside in a contiguous block of memory in the format shown in the table. That is to say that the first descriptor of the next descriptor set must be located in the memory location immediately following the last descriptor of the current descriptor set. The values have the same order as the corresponding MMR offset addresses.

**Table 13-10:** Parameter Registers and Descriptor Offsets

**Table 13-11:**

| Descriptor Offset | Parameter Register |
|-------------------|--------------------|
| 0x00              | DMA_ADDRSTART      |
| 0x04              | DMA_CFG            |
| 0x08              | DMA_XCNT           |
| 0x0C              | DMA_XMOD           |
| 0x10              | DMA_YCNT           |
| 0x14              | DMA_YMOD           |

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. All of the current registers are reloaded between the descriptor set fetch and the start of the DMA operation for the work unit.

## Minimum Startup Requirements

At a minimum the DMA\_DSCPTR\_CUR register must be written prior to writing to the DMA\_CFG register, which is the special action required to start the DMA channel.

## DMA Channel Descriptor On Demand List Mode

In this flow mode, multiple descriptors form a chained list in which each descriptor set contains a pointer to the next descriptor set, allowing greater flexibility in memory layout options. When the descriptor set is fetched, this pointer value is loaded into the DMA channels next descriptor pointer register.

At the end of the work unit, if the DMA channel has not detected an incoming trigger event, the current work unit is repeated. If the DMA channel receives an incoming trigger before completion of the work unit then a new descriptor set is fetched.

## Descriptor Sets

The [Descriptor List Mode Parameter and Descriptor Offsets](#) illustrates how a descriptor set must be structured in memory. Note that while the descriptor sets can be dispersed throughout memory and reside in different memory blocks, each descriptor of the descriptor set must reside in a contiguous section of memory in the format shown in the table. The values have the same order as the corresponding MMR offset addresses.

**Table 13-12:** Descriptor List Mode Parameter and Descriptor Offsets

**Table 13-13:**

| Descriptor Offset | Parameter Register |
|-------------------|--------------------|
| 0x00              | DMA_DSCPTR_NXT     |
| 0x04              | DMA_ADDRSTART      |
| 0x08              | DMA_CFG            |
| 0x0C              | DMA_XCNT           |
| 0x10              | DMA_XMOD           |
| 0x14              | DMA_YCNT           |
| 0x18              | DMA_YMOD           |

All other DMA channel registers not loaded as a result of the descriptor set fetch retain their previous values. All of the register's current values are reloaded between the descriptor set fetch and the start of the DMA operation for the work unit.

## Minimum Startup Requirements

At a minimum the DMA\_DSCPTR\_NXT register must be written prior to write to the DMA\_CFG register which is the special action required to start the DMA channel.

## DMA Channel Data Transfer Modes

The DMA channel, in addition to supporting basic one-dimensional DMA transfers, also supports two-dimensional functionality.

## DMA Channel Two-Dimensional DMA

Register-based and descriptor-based DMA flow modes support two-dimensional data transfers.

In two-dimensional (2D) mode the X directional count and modifier (DMA\_XCNT and DMA\_XMOD) registers are accompanied by the Y directional count and modifier (DMA\_YCNT and DMA\_YMOD) registers, supporting arbitrary row and column sizes. Furthermore, modify values can be negative, allowing implementation of interleaved data streams. DMA\_XCNT and DMA\_YCNT specify the row and column sizes respectively, where the DMA\_XCNT must be 2 or greater.

The DMA start address (DMA\_STARTADDR) register, along with DMA\_XMOD and DMA\_YMOD registers, are all specified in bytes, and they must be aligned to a multiple of the DMA transfer word size as configured by the DMA\_CFG.MSIZE bit. Misalignment results in a DMA channel error.

The DMA\_XMOD register value is the byte-address increment that is applied after each transfer that decrements the DMA\_XCNT register. The DMA\_XCNT register is not applied when the inner loop count is ended by the DMA\_XCNT\_CUR register decrementing to 0 from 1, except that it is applied on the final transfer when the DMA\_YCNT register is 1 and the DMA\_XCNT register decrements from 1 to 0.

The DMA\_YMOD register value is the byte-address increment that is applied after each decrement of the value in the DMA\_YCNT\_CUR register. However, the DMA\_YMOD value is not applied to the last item in the array on which the outer loop count (DMA\_YCNT\_CUR) also expires by decrementing from 1 to 0.

After the last transfer completes, DMA\_YCNT\_CUR is 1 and the DMA\_XCNT\_CUR register is 0. The DMA channels current address points to the last items address plus the DMA\_XMOD register value. Note that if the DMA channel is programmed to refresh automatically such as in autobuffer mode, then both the DMA\_XCNT\_CUR and DMA\_YCNT\_CUR registers and the DMA current address (DMA\_ADDR\_CUR) are reloaded for the first data transfer of the next work unit.

Interrupt notification is configurable for end of row or end of work unit completion.

## DMA Channel Event Control

The DMA channel supports a number of events to provide notification of work unit state, peripheral data request, peripheral data request and completion events, and DMA channel error conditions. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

The DMA channel has two interrupt signals for support of a number of events such as work unit state events, Peripheral Interrupt Request (PIRQ) events, Peripheral Data Request (PDR) events and DMA channel errors. DMA channel errors are reported on a dedicated interrupt signal while all other interrupt sources share the same interrupt signal. In addition to flexible interrupt configuration, the DMA channel also supports incoming and outgoing triggers which are useful in synchronizing the DMA channel with other system resources.

DMA channel events can be signaled to the processor using status information and optional interrupt requests. These events may be used for progress updates of data transfers and to request intervention from the processor core. A majority of DMA channel interrupts are configured by the respective bits in the DMA\_CFG register. Dedicated bits in the DMA\_STAT register are used to report the occurrence of various events. Interrupt requests are cleared by write-one-to-clear (W1C) operations to the status register.

**NOTE:** Hardware does not clear the interrupt status bits automatically even if the DMA channel is disabled then re-enabled. In this situation the interrupt signal from the DMA channel is de-asserted once the DMA channel is disabled, but the status bit remains set until the DMA channel is enabled again or cleared by software.

The DMA channel supports the following categories of events on the interrupt signals.

- Work unit state events are used to generate interrupts on row or on work unit DMA completion.
- Peripheral Interrupt Request (PIRQ) events are signaled by the peripheral when it has completed the transfer of all data.
- Peripheral Data Request (PDR) events for when the DMA channel is disabled or idle and the peripheral is requesting data from the DMA channel.
- Error events due to a failure in the work unit.

**ATTENTION:** The DMA channel will not generate an interrupt to the processor for a work unit state event, PIRQ event or forward a PDR event while in an error state.

## Event Signals

The *Event Signals* table provides descriptions of DMA channel events

**Table 13-14:** Event Signals

| Signal        | Width (bits) | Description                                                                                                                                                                                                       |
|---------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DMA_ERROR     | 1            | Used to signal an error condition in the DMA channel. The source of the error can be determined by reading DMA_STAT.ERRC                                                                                          |
| DONE_PIRQ_INT | 1            | Signal used to indicate DMA completions events, PIRQ events and also for forwarding PDR events based on configuration. The source of the event may be determined by reading the corresponding fields in DMA_STAT. |
| DMA_TRIG_OUT  | 1            | Trigger output that gets routed to the TRU and can be configured to provide notification on row or work unit completion.                                                                                          |
| DMA_TRIG_IN   | 1            | Trigger input from the TRU that can be used to control the start of a work unit.                                                                                                                                  |

## Work Unit State Events

Work unit state events are generated as a result of a row or a work unit completion. In order for either of these events to result in the generation of an interrupt, the interrupt of the DMA channel must be configured for one of the available work unit completion modes.

- Current X count reaching 0 for row completion or 1-D DMA work unit completion.
- Current Y count reaching 0 for work unit completion of 2-D DMA.

**NOTE:** For one -dimensional DMA, configuring the interrupt to be generated on the current Y counter reaching 0 results in a DMA channel configuration error.

The DMA channel issues the last memory read or write transaction for the row or work unit and then pauses until the read or write acknowledge is returned. Once the transfer has been acknowledged successfully the DMA channel issues the interrupt and continues to process the next row or work unit.

Waiting for the memory access to be acknowledged results in a delay. However, programs can read or modify data in the memory without adversely affecting, or being affected by, the DMA transfer.

**NOTE:** While the DMA channel may be paused waiting for the memory transfer to be acknowledged, the DMA channel is still capable of fetching the next descriptor set in order to be ready to process the next work unit as soon as the memory access completes.

The interrupt timing is also affected by the synchronization feature of the DMA channel's configuration. For memory read operations with synchronization enabled, the interrupt is delayed further until the last transfer from the DMA channel's FIFO to the peripheral completes. The interrupt timing for memory write operations is not affected by the synchronization feature.

## Peripheral Interrupt Request Events

Peripheral Interrupt Request (PIRQ) events may be used by a peripheral connected to the DMA channel to indicate, in the case of a peripheral transmit operation, that data has not only left the FIFO of the DMA channel, but that the peripheral has also completed the transfer.

In order to support PIRQ interrupts the DMA channel's interrupt must be configured accordingly. This disables the generation of interrupts based on work unit state and instead results in the generation an interrupt when the DMA channel receives the command from the peripheral.

The interrupt is only generated if the following conditions are satisfied.

- The DMA channel is enabled
- The DMA channel is in the stop state
- The DMA channel's interrupt is configured for PIRQ operation

## Peripheral Data Request Events

Peripheral Data Request (PDR) events occur when an interfaced peripheral requests data from the DMA channel and the DMA channel is either disabled or enabled and in the stop state.

When the DMA channel is disabled and a peripheral sends a command to the DMA channel to request data, the DMA channel generates an interrupt to the System Event Controller (SEC). There is no status information reported about this event in the DMA channel's status register. Instead, the PDR event is identified by the fact that the DMA channel generated an interrupt when it was disabled. Further confirmation can be obtained by verifying the status of the peripheral interfaced to the DMA channel.

In addition to requests for data being forwarded as interrupts when the DMA channel is in the disabled state, the DMA channel is also able to forward PDR events as an interrupt when the DMA channel is in the stop state after completion of a work unit. The forwarding of this interrupt when the DMA channel is in the stop state is optional and configured by the program during DMA channel configuration.

## DMA Channel Triggers

DMA channel triggers are useful for synchronizing the DMA channel with other events in the system. Channel triggers can be used in combination with each other in order to create ping-pong buffers or when combined with interrupts to notify the processor that a particular milestone has been reached and that service is required. Triggers may also be used to enforce a handshake DMA operation in which the trigger acts as a signal for a DMA request.

**NOTE:** Using the trigger to control the pace of data transfers, such as in the case of a handshake DMA, requires that all the data for the entire work unit is ready for transfer.

The DMA channel has a single incoming trigger that can be used to control the pace of the data transfers performed by the DMA channel. The DMA channel can be configured to wait for the incoming trigger before starting the work unit transfer or fetching a descriptor set from memory.

The DMA channel also has a single outgoing trigger signal that may be configured to signal the end of row or an entire work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, and then pauses until the transfer acknowledge is returned. Once the transfer has been acknowledged, the DMA channel issues the trigger before processing the next row or work unit.

## Issuing Triggers

The DMA channel can be configured to generate an outgoing trigger signal at the end of row or the end of a work unit. The DMA channel issues the last memory read or memory write transaction for the row or work unit, and then pauses until the transfer acknowledge is returned. Once the transfer has been acknowledged the DMA channel issues the trigger before processing the next row or work unit.

**NOTE:** While the DMA channel may be paused while waiting for the memory transfer to be acknowledged, the DMA channel is still capable of fetching the next descriptor set in order to be ready to process the next work unit as soon as the memory access completes.

## Waiting For Triggers

Triggering may be used to control the pace of data transfers performed by the DMA channel. If `DMA_CFG.TWAIT` is enabled and a trigger has been received since the last time the DMA channel left the wait state or since transition from disabled to enabled, then the DMA channel will enter a wait state before beginning the next work unit. The DMA channel will not perform a descriptor fetch either. Once a trigger is received, the DMA channel will leave the wait state and begin the next work unit or fetch the next descriptor if configured for a descriptor based mode of operation.

If the DMA channel is programmed through a memory mapped register write operation with stop flow mode enabled, `DMA_CFG.TWAIT` enabled and no trigger having already been received, then the DMA channel will enter a wait state before performing the data transfer. Upon receiving the trigger, the DMA channel will begin the data transfer portion of the work unit. Once the data transfer is complete, the DMA channel will enter the stop state.

If the DMA channel is programmed through a memory mapped register write operation with the flow mode configured to one of the descriptor based modes, then the DMA channel will enter wait state before performing the descriptor fetch. Once the descriptor fetch is complete, the DMA channel immediately proceeds to the data transfer, regardless of the value of the `DMA_CFG.TWAIT` bit. If the descriptor fetch is followed by another descriptor fetch, then the DMA channel enters a wait state before fetching the next descriptor.

If the descriptor fetch returns a descriptor with stop flow mode then the `DMA_CFG.TWAIT` value for that descriptor will not affect the DMA as the DMA channel will enter the stop state once the data transfer is completed. The DMA channel only enters the wait state based on `DMA_CFG.TWAIT` before the next work unit or descriptor fetch.

If the descriptor fetch returns a descriptor configured for Autobuffer flow mode, then `DMA_CFG.TWAIT` for that descriptor will not affect the DMA for the first work unit of the autobuffer transfer. Once the first work unit is completed another trigger has not been received, then the DMA channel will enter the wait state before re-initializing its counters and address registers if not configured for current addressing. The next work unit is performed once the trigger is received.

The incoming trigger does not have to be issued after the DMA channel has entered the wait state, and can be issued whilst the DMA channel is in the midst of executing a work unit, descriptor fetch or even when in the stop state. the trigger will be held internally, and once the work unit is complete, the DMA channel will skip the wait state and proceed directly to executing the following work unit. If `DMA_CFG.TWAIT` is not enabled, the DMA channel will also skip the wait state, however the trigger will be held internally and used the next time `DMA_CFG.TWAIT` is enabled. This allows the user to enable the `DMA_CFG.TWAIT` functionality several work units apart and not be concerned with losing a trigger. The DMA channels trigger overrun enable functionality may be enabled in all work units to ensure multiple triggers do not occur between the work units with `DMA_CFG.TWAIT` enabled.

## DMA Channel Programming Model

Several synchronization and control methods are available for use in development of software tasks which manage peripheral DMA and memory DMA. Such software needs to be able to accept requests for new DMA transfers from other software tasks, integrate these transfers into existing transfer queues, and reliably notify other tasks when the transfers are complete.

In the processor, it is possible for each peripheral DMA and memory DMA stream to be managed by a separate task or to be managed together with any other stream. Each DMA channel has independent, orthogonal control registers, resources, and interrupts, so that the selection of the control scheme for one channel does not affect the choice of control scheme on other channels. For example, one peripheral can use a linked-descriptor-list, interrupt-driven scheme while another peripheral can simultaneously use a demand-driven, buffer-at-a-time scheme synchronized by polling of DMA events.

The topics that follow describe the steps required to configure the DMA channel for the various modes in addition to the programming concepts required for software synchronization.

## DMA Channel Mode Configuration

Use the step-by-step directions that follow to set up the DMA channel for operating modes. These directions include flowcharts and links to reference information where appropriate.

### Register Based Linear Buffer Stop Flow Mode

Configures a peripheral's DMA channel to read data from internal memory and send it to the peripheral for transmission.

#### *PREREQUISITE:*

The peripheral is assumed to be in a state where it is ready to transmit data received from the DMA channel.

The task involves writing to a number of DMA channel MMR registers in order to configure a DMA channel to read data from internal memory and send it to a peripheral connected to the peripheral DMA bus. Upon DMA completion the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_ADDRSTART` register.

*ADDITIONAL INFORMATION:* The address may be used to calculate the most optimum `DMA_CFG.MSIZE` possible.

2. Calculate most optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

*ADDITIONAL INFORMATION:* The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

3. Write the `DMA_XCNT` register based on calculated `DMA_CFG.MSIZE`.

*ADDITIONAL INFORMATION:* `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers required to make up the entire work unit.

4. Write the `DMA_XMOD` register.

*ADDITIONAL INFORMATION:* For a completely linear buffer transfer, `DMA_XMOD` is determined by the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

5. Write the `DMA_CFG` register with `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for STOP mode, `DMA_CFG.WNR` must be configured for memory read operation and `DMA_CFG.PSIZE` must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

- `DMA_CFG.SYNC` may be configured to control DMA completion notification timing.
- Interrupts and triggers may also be configured at this step depending on requirements.

*RESULT:*

The DMA channel is now enabled and the buffer is transferred. The DMA channel enters the IDLE state upon completion of the work unit.

## Register Based Autobuffer Flow Mode

Configures a peripherals' DMA channel to read data from internal memory and send it to the peripheral for transmission. The transmission of the buffer is repeated endlessly.

*PREREQUISITE:*

The peripheral is assumed to be in a state where it is ready to transmit data received from the DMA channel

The task involves writing to a number of DMA channel MMR registers in order to configure a DMA channel to read data from internal memory and send it to a peripheral connected to the peripheral DMA bus. Upon DMA completion the DMA channel starts the DMA operation over again creating an endless circular buffer transfer.

1. Write the `DMA_ADDRSTART` register.

*ADDITIONAL INFORMATION:* The address may be used to calculate the most optimum `DMA_CFG.MSIZE` possible.

2. Calculate most optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

*ADDITIONAL INFORMATION:* The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

3. Write the `DMA_XCNT` register based on calculated `DMA_CFG.MSIZE`.

*ADDITIONAL INFORMATION:* `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers required to make up the entire work unit.

4. Write the `DMA_XMOD` register.

*ADDITIONAL INFORMATION:* For a completely linear buffer transfer, `DMA_XMOD` is determined by the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

5. Write the `DMA_CFG` register with the `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for AUTOBUFFER mode, `DMA_CFG.WNR` must be configured for memory read operation and `DMA_CFG.PSIZE` must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

- `DMA_CFG.SYNC` may be configured to control DMA completion notification timing.
- Interrupts and triggers may also be configured at this step depending on requirements.

*RESULT:*

The DMA channel is now enabled and the buffer is transferred until the DMA channel is disabled.

## Descriptor Array Flow Mode

Configures a peripheral's DMA channel to read data from memory as described by the descriptor sets in the array and send it to the peripheral for transmission. Descriptor sets are read from an array in memory to configure the individual work units.

*PREREQUISITE:*

The peripheral is assumed to be in a state where it is ready to transmit data received from the DMA channel. The array of descriptors is assumed to be initialized with the last descriptor set configured for STOP flow mode.

The task involves writing to a number of DMA channel MMR registers in order to configure a DMA channel to read the first descriptor set from the array in memory that is responsible for the configuring the DMA channel to retrieve and send the data to a peripheral connected to the peripheral DMA bus. Upon

DMA completion the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_DSCPTR_CUR` register with the address of the array in which the descriptor sets are stored.

*ADDITIONAL INFORMATION:* The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the `DMA_CFG` register with the `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for DESCRIPTOR ARRAY mode, `DMA_CFG.NDSIZE` must be configured to describe the number of descriptor elements contained within the first descriptor set. `DMA_CFG.WNR` must be configured for memory read operation and `DMA_CFG.PSIZE` must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

- `DMA_CFG.SYNC` configuration is controlled by the descriptor set that is to be fetched as are interrupt and trigger configurations

*STEP RESULT:* The first descriptor set is fetched from memory location provided by `DMA_DSCPTR_CUR` and loaded to the DMA Channels MMR registers.

*RESULT:*

The DMA channel is now processing all the work units provided in the descriptor array. The DMA channel enters the IDLE state upon completion of the final work unit that was configured for STOP flow mode.

## Descriptor List Flow Mode

Configures a peripheral's DMA channel to read data from memory as described by the descriptor sets in the list and send it to the peripheral for transmission. Descriptor sets are read from a list of descriptors in which each descriptor set has a descriptor that points to the next descriptor set location in memory.

*PREREQUISITE:*

The peripheral is assumed to be in a state where it is ready to transmit data received from the DMA channel. The list of descriptors is assumed to be initialized with the last descriptor set in the list configured for STOP flow mode.

The task involves writing to a number of DMA channel MMR registers in order to configure a DMA channel to read the first descriptor set from the list in memory that is responsible for the configuring the DMA channel to retrieve and send the data to a peripheral connected to the peripheral DMA bus. Upon

DMA completion the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_DSCPTR_NXT` register with the address of the first descriptor in the list to be processed.

*ADDITIONAL INFORMATION:* The array address must meet any processor alignments restrictions imposed by descriptor fetches.

2. Write the `DMA_CFG` register with the `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for DESCRIPTOR LIST mode, and the `DMA_CFG.NDSIZE` bit must be configured to describe the number of descriptor elements contained within the first descriptor set. The `DMA_CFG.WNR` bit must be configured for memory read operation and the `DMA_CFG.PSIZE` bit must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

- `DMA_CFG.SYNC` configuration is controlled by the descriptor set that is to be fetched as are interrupt and trigger configurations.

*STEP RESULT:* The first descriptor set is fetched from the memory location provided by `DMA_DSCPTR_NXT` and loaded to the DMA channel's MMR registers.

*RESULT:*

The DMA channel is now processing all the work units provided in the descriptor list. The DMA channel enters the IDLE state upon completion of the final work unit that was configured for STOP flow mode.

## Register Based Memory to Memory Transfer in Stop Flow Mode

Configures a memory DMA channel pair in STOP flow mode. One DMA channel is configured for memory read operations while the other is configured for memory write.

*PREREQUISITE:*

The task involves writing to a number of DMA channels on two DMA channels that create a memory DMA pair. Upon DMA completion the DMA channel enters the idle state until either disabled or reconfigured for a new transfer.

1. Write the `DMA_ADDRSTART` register of the source DMA channel.

*ADDITIONAL INFORMATION:* The address may be used to calculate the most optimum `DMA_CFG.MSIZE` possible.

2. Calculate most optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

*ADDITIONAL INFORMATION:* The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

3. Write the `DMA_XCNT` register of the source DMA channel based on calculated `DMA_CFG.MSIZE`.

*ADDITIONAL INFORMATION:* `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers required to make up the entire work unit.

4. Write the `DMA_XMOD` register of the source DMA channel.

*ADDITIONAL INFORMATION:* For a completely linear buffer transfer, `DMA_XMOD` is determined by the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

5. Write the `DMA_ADDRSTART` register of the destination DMA channel.

*ADDITIONAL INFORMATION:* The address may be used to calculate the most optimum `DMA_CFG.MSIZE` possible.

6. Calculate most optimum `DMA_CFG.MSIZE` based on the `DMA_ADDRSTART` register and number of bytes in work unit.

*ADDITIONAL INFORMATION:* The number of bytes in the work unit must be a multiple of the selected `DMA_CFG.MSIZE` and the start address alignment must also be considered.

7. Write the `DMA_XCNT` register of the destination DMA channel based on calculated `DMA_CFG.MSIZE`.

*ADDITIONAL INFORMATION:* `DMA_XCNT` is the number of `DMA_CFG.MSIZE` transfers required to make up the entire work unit.

8. Write the `DMA_XMOD` register of the destination DMA channel.

*ADDITIONAL INFORMATION:* For a completely linear buffer transfer, `DMA_XMOD` is determined by the selected `DMA_CFG.MSIZE`. This register is always specified in the number of bytes.

9. Write the `DMA_CFG` register of the source DMA channel with `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for STOP mode, `DMA_CFG.WNR` must be configured for memory read operation and `DMA_CFG.PSIZE` must be configured to a value no larger than the supported bus width of the peripheral DMA bus.

- `DMA_CFG.SYNC` may be configured to control DMA completion notification timing.
- Interrupts and triggers may also be configured at this step depending on requirements, generally however they would be enabled within the destination DMA channel configuration.

*STEP RESULT:* The memory read DMA transfer begins.

10. Write the `DMA_CFG` register of the destination DMA channel with `DMA_CFG.EN` configured to enable the DMA channel.

*ADDITIONAL INFORMATION:* `DMA_CFG.FLOW` must be set for STOP mode, `DMA_CFG.WNR` must be configured for memory write operation and `DMA_CFG.PSIZE` must be configured to a value no larger than the

supported bus width of the peripheral DMA bus. This must also match the value written for the source DMA channel configuration.

- Interrupts and triggers may also be configured at this step depending on requirements.

*STEP RESULT:* The memory write DMA transfer begins.

*RESULT:*

Both memory DMA channels are now running and the data is transferred from the source address to the destination address. The DMA channel enters the IDLE state upon completion of the work unit.

## **DMA Channel Programming Concepts**

Using the features, operating modes, and event control for the DMA channel to their greatest potential requires an understanding of some DMA channel related concepts.

### **Synchronization of Software and DMA**

A critical element of software DMA management is synchronization of DMA work unit completion with the software. This can best be achieved using DMA channel interrupt and trigger events, or through polling of these events status bits within the DMA channel registers, or a combination of both. Polling for address or count can only provide synchronization within loose tolerances comparable to pipeline lengths.

#### **Interrupt and Trigger Event Based Synchronization**

Interrupt and trigger based synchronization methods must avoid interrupt/trigger overrun, or the failure to invoke a DMA channel's event handler for every event due to excessive latency in processing of events. Generally, the system design must either ensure that only one event per channel is scheduled (for example, at the end of a descriptor list), or that generated events are spaced sufficiently far apart in time that system processing budgets can guarantee every event is serviced.

When the DMA channel issues an interrupt/trigger event or changes event status bits in the DMA\_STAT register, it guarantees that the last memory operation of the work unit is complete. For memory read DMA transactions, this means that the final memory read data has been safely received in the DMA channel's FIFO. For memory write DMA transactions, this means that the DMA channel has received an acknowledge that the last write transfer of the work unit has completed.

#### **Register Polling Based Synchronization**

Polling of DMA channel registers such as the DMA\_ADDR\_CURR, DMA\_DSCPTR\_CURR, or DMA\_XCNT\_CURR/DMA\_YCNT\_CURR registers is not recommended as a method of precisely synchronizing DMA with data processing, due to DMA channel FIFOs and DMA/memory pipelining. The current address, pointer, and count registers change several cycles in advance of the completion of the corresponding memory operation, as measured by the time at which the results of the operation are first visible to the core by memory read or write instructions.

For example, in a DMA channel memory write operation to external memory, assume a DMA channel write operation is initiated by DMA channel A. This causes the DDR SDRAM to perform a page open operation which takes many system clock cycles. Meanwhile, another DMA channel (channel B) which does not in itself incur latency, initiates a transfer that is stalled behind the slow operation of channel A. Software monitoring channel B could not safely conclude whether the memory location pointed to by channel B's `DMA_ADDR_CURR` register has or has not been written, based solely on this register contents.

Polling of the current address, pointer, and count registers can permit loose synchronization of DMA with software if allowances are made for the lengths of the DMA/memory pipeline. Further, the length of the DMA FIFO for a particular peripheral needs to be taken into consideration. The DMA channel does not advance current address/pointer/count registers if these FIFOs are filled with incomplete work (including reads that have been started but not yet finished).

Additionally, the length of the pipelines to the destination memory needs to be taken into consideration. If the DMA FIFO length and the DMA channel's memory pipeline length are added, an estimate can be made of the maximum number of incomplete memory operations in progress at one time.

*The estimate would be a maximum, as the DMA/memory pipeline may include traffic from other DMA channels.*

## Descriptor Queues

A system designer might want to write a DMA manager facility which accepts DMA requests from other software. The DMA manager software does not know in advance when new work requests are received or what these requests might contain. The software could manage these transfers using a circular linked list of DMA descriptors, where each descriptor sets `DMA_DSCPTR_NXT` descriptor points to the next descriptor set, and the last descriptor set points to the first.

The code that writes into this descriptor list could use the processor's circular addressing modes, so that it does not need to use comparison and conditional instructions to manage the circular structure. In this case, the `DMA_DSCPTR_NXT` descriptor of each descriptor set could even be written once at startup, and skipped over as each descriptor's new contents are written.

The recommended method for synchronization of a descriptor queue is through the use of an interrupt or trigger. The descriptor queue is structured so that at least the final valid descriptor set is always programmed to generate an interrupt or trigger event upon completion.

- [Queues Using Event Generation for Every Descriptor Set](#)
- [Queues Using Minimal Events](#)

### Queues Using Event Generation for Every Descriptor Set

In this system, the DMA manager software synchronizes with the DMA channel by enabling an interrupt or trigger on every descriptor set. This method should only be used if the system design can guarantee that each work unit completion event is serviced separately (no interrupt or trigger overrun).

To maintain synchronization of the descriptor set queue, the non-interrupt software maintains a count of descriptor sets added to the queue, while the event handler (either interrupt or trigger) maintains a count of completed descriptor sets removed from the queue. The counts are equal only when the DMA channel is paused after having processed all the descriptor sets.

When each new work unit event is received, the DMA manager software initializes a new descriptor set, taking care to set the flow to STOP mode. Next, the software compares the descriptor set counts to determine if the DMA channel is running or not. If the DMA channel is paused (counts equal), the software increments its count and then starts the DMA channel by writing the new descriptor sets' DMA\_CFG descriptor.

If the counts are unequal, the software instead modifies the next-to-last descriptor sets' DMA\_CFG descriptor so that it now describes the newly-queued descriptor set. This operation does not disrupt the DMA channel provided the rest of the descriptor sets' descriptors are initialized in advance. It is necessary, however, to synchronize the software to the DMA to correctly determine whether the new or the old DMA\_CFG value was read by the DMA channel.

The synchronization operation should be performed in the event handler. First, when an event is detected, the handler should read the channel's DMA\_STAT register. If DMA\_STAT.RUN indicates the DMA channel is running, then the channel has moved on to processing another descriptor, and the event handler may increment its count and exit. If DMA\_STAT.RUN indicates the channel is not running, then the channel is paused, either because there are no more descriptor sets to process, or because the last descriptor set was queued too late (that is, the modification of the next-to-last descriptor sets' DMA\_CFG descriptor occurred after that descriptor was read into the DMA channel). In this case, the event handler writes the DMA\_CFG value appropriate for the last descriptor set to the DMA channel's DMA\_CFG register, increments the completed descriptor count, and exits.

Again, this system can fail if the system's event latencies are large enough to cause any of the channel's DMA events to be dropped. An event handler capable of safely synchronizing multiple descriptor set interrupts is complex, performing several MMR accesses to ensure robust operation. In such a system environment a minimal event synchronization method is preferred.

## **Queues Using Minimal Events**

In this system, only one DMA interrupt or trigger event is generated in the queue at any time. The DMA event handler for this system can also be extremely short. Here, the descriptor queue is organized into an *active* and a *waiting* portion, where events are enabled only on the last descriptor set in each portion.

When each new DMA request is processed, the software fills in a new descriptor set's contents and adds it to the waiting portion of the queue. The descriptor set's DMA\_CFG descriptor should have the flow set to Stop mode. If more than one request is received before the DMA queue completion event occurs, the non-interrupt code queues later descriptor sets, forming a waiting portion of the queue that is disconnected from the active portion of the queue being processed by the DMA channel. In other words, all but the last active descriptor sets contain FLOW values for a descriptor based mode and have no event enable set. The last active descriptor set has the Stop flow mode and an event generation enabled. Also, all but the last waiting descriptor sets are configured for descriptor based flow modes with no event generation. Only the last waiting descriptor set is configured for Stop flow mode and event generation enabled. This ensures

that the DMA channel can automatically process the whole active queue before then issuing one event. Also, this arrangement makes it easy to start the waiting queue within the event handler by a single `DMA_CFG` register write.

After queuing a new waiting descriptor, the non-interrupt software leaves a message for its interrupt handler in a memory mailbox location containing the desired `DMA_CFG` value to use to start the first waiting descriptor set in the waiting queue (or 0 to indicate no descriptors are waiting).

It is critical that the software not modify the contents of the active descriptor set queue directly, once processing by the DMA channel has started, unless careful synchronization measures are taken. In the most straightforward implementation of a descriptor set queue, the DMA manager software never modifies descriptors on the active queue; instead, the DMA manager waits until the DMA queue completion event indicates the processing of the entire active queue is complete.

When a DMA queue completion event is received, the event handler reads the mailbox from the non-interrupt software and writes the value to the DMA channel's `DMA_CFG` register. This single register write restarts the queue, effectively transforming the waiting queue to an active queue. The event handler then passes a message back to the non-interrupt software indicating the location of the last descriptor set accepted into the active queue. If, on the other hand, the event handler reads its mailbox and finds a `DMA_CFG` value of zero, indicating there is no more work to perform, then it passes an appropriate message back to the non-interrupt software indicating that the queue has stopped.

The non-interrupt software which accepts new DMA work unit requests needs to synchronize the activation of a new work unit with the interrupt handler. If the queue has stopped (that is, if the mailbox from the event handler is zero), the non-interrupt software is responsible for starting the queue (writing the first descriptor sets `DMA_CFG` value to the channel's `DMA_CFG` register). If the queue is not stopped, the non-interrupt software must not write the `DMA_CFG` register (which would cause a DMA error), but instead it should queue the descriptor onto the waiting queue and update its mailbox directed to the event handler.

## DMA Register Descriptions

DMA Channel (DMA) contains the following registers.

**Table 13-15:** DMA Module Registers

| Name                        | Description                        |
|-----------------------------|------------------------------------|
| <code>DMA_DSCPTR_NXT</code> | Pointer to Next Initial Descriptor |
| <code>DMA_ADDRSTART</code>  | Start Address of Current Buffer    |
| <code>DMA_CFG</code>        | Configuration Register             |
| <code>DMA_XCNT</code>       | Inner Loop Count Start Value       |

**Table 13-15:** DMA Module Registers (Continued)

| Name           | Description                              |
|----------------|------------------------------------------|
| DMA_XMOD       | Inner Loop Address Increment             |
| DMA_YCNT       | Outer Loop Count Start Value (2D only)   |
| DMA_YMOD       | Outer Loop Address Increment (2D only)   |
| DMA_DSCPTR_CUR | Current Descriptor Pointer               |
| DMA_DSCPTR_PRV | Previous Initial Descriptor Pointer      |
| DMA_ADDR_CUR   | Current Address                          |
| DMA_STAT       | Status Register                          |
| DMA_XCNT_CUR   | Current Count(1D) or intra-row XCNT (2D) |
| DMA_YCNT_CUR   | Current Row Count (2D only)              |
| DMA_BWLCNT     | Bandwidth Limit Count                    |
| DMA_BWLCNT_CUR | Bandwidth Limit Count Current            |
| DMA_BWMCNT     | Bandwidth Monitor Count                  |
| DMA_BWMCNT_CUR | Bandwidth Monitor Count Current          |

## Pointer to Next Initial Descriptor

The DMA\_DSCPTR\_NXT register specifies the start location of the next descriptor set, which begins when the DMA activity specified by the current descriptor set completes. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

The DMA\_DSCPTR\_NXT register is only used in descriptor list mode. At the start of a descriptor fetch in this mode, the DMA\_DSCPTR\_NXT register is copied into the DMA\_DSCPTR\_CUR register. During descriptor fetch, the DMA increments the DMA\_DSCPTR\_CUR register value after reading each element of the descriptor set.

In descriptor list mode, the DMA\_DSCPTR\_NXT register (not the DMA\_DSCPTR\_CUR register) must be programmed directly through MMR access, before the DMA operation is started. In descriptor array mode, the DMA disregards the DMA\_DSCPTR\_NXT register and uses the DMA\_DSCPTR\_CUR register to control descriptor fetch.

DMA\_DSCPTR\_NXT: Pointer to Next Initial Descriptor - R/W

Reset = 0x0000 0000

Figure 13-4: DMA\_DSCPTR\_NXT Register Diagram

Table 13-16: DMA\_DSCPTR\_NXT Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 31:0    | VALUE    | Pointer To Next Descriptor Set. |

Start Address of Current Buffer

The DMA\_ADDRSTART register contains the start address of the Work Unit currently targeted for DMA. This register is read/write prior to enabling the channel, but is read-only after enabling channel.

DMA\_ADDRSTART: Start Address of Current Buffer - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration        |
|---------|----------|--------------------------------|
| 31:0    | VALUE    | Work Unit address start value. |

Configuration Register

The DMA\_CFG sets up DMA parameters and operation modes. Other than clearing the DMA\_CFG.EN bit, writing to the DMA\_CFG register while a DMA process is already running cause a DMA error.

| 23:22   | TRIG     | <p>Generate Outgoing Trigger.</p> <p>The DMA_CFG.TRIG selects whether the DMA issues an outgoing trigger, based on the work unit counter values. In one-dimensional mode, the only options are to trigger at the end of the whole Work Unit (trigger when DMA_XCNT_CUR reaches 0) or not to trigger at all. If in one-dimensional addressing mode, programming DMA_CFG.TRIG to trigger when DMA_YCNT_CUR reaches 0 (or to reserved) cause the DMA to flag a configuration error.</p> <p>If in two-dimensional addressing mode, the options are to trigger at the end of each row of the inner loop (when DMA_XCNT_CUR reaches 0), to trigger only after completing the whole work unit (when DMA_YCNT_CUR reaches 0), or not to trigger at all. If in two-dimensional mode and set to trigger when DMA_XCNT_CUR reaches 0, the DMA also issues a trigger at the end of the work unit. If in two-dimensional addressing mode, programming DMA_CFG.TRIG to reserved causes the DMA to flag a configuration error.</p> <p>If DMA_CFG.TRIG is non-zero and the peripheral issues a finish command, the DMA issues a trigger after the finish procedure is complete.</p> <p>For more information about trigger generation timing, see the trigger section of the DMA functional description.</p> |

| 18:16   | NDSIZE   | Next Descriptor Set Size.<br>The <code>DMA_CFG.NDSIZE</code> specifies the number of descriptor elements in memory to load during the next descriptor fetch. The DMA loads the descriptors in a specific order. The descriptor set may or may not have the next descriptor pointer, depending on whether it is a descriptor list or descriptor array.                                                                                                                                                                    |
|         |          | 0 Fetch one Descriptor Element                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1 Fetch two Descriptor Elements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 15      | TWAIT    | Wait for Trigger.<br>The <code>DMA_CFG.TWAIT</code> controls whether the DMA waits for a incoming trigger from another channel or user. If <code>DMA_CFG.TWAIT</code> is set, the DMA enters the wait state before starting the next work unit, including descriptor fetch if in descriptor mode. Using the wait for trigger control is not allowed for descriptor-on-demand mode, and using this control in that mode causes an error. For more information, see the trigger section of the DMA functional description. |
|         |          | 0 Begin Work Unit Automatically (No Wait)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14:12   | FLOW     | Next Operation.<br>The DMA_CFG.FLOW selects descriptor handling options.                                                                                                                                                                                                                                                                                                                                                                                                                          |
|         |          | 0<br>STOP - Stop<br>When the current work unit completes, the DMA channel stops automatically, after signaling an interrupt (if selected). The DMA_STAT.RUN status bit changes to idle, while DMA_CFG.EN bit is unchanged. In this state, the channel is stopped. Peripheral interrupts are still filtered out by the DMA. The channel may be restarted simply by another write (with the DMA_CFG.EN set) to the DMA_CFG register specifying the next work unit.                                  |
|         |          | 1<br>AUTO - Autobuffer<br>In this mode, no descriptors in memory are used. Instead, DMA is performed in a continuous circular buffer fashion based on user programmed DMA MMR settings. On completion of the work unit, the parameter registers are reloaded into the current registers, and DMA resumes immediately with zero overhead. This mode is considered to be a succession of automatically restarted work units. Autobuffer mode is stopped by a user write of 0 to the DMA_CFG.EN bit. |
|         |          | 2<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         |          | 3<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         |          | 4<br>DSCL - Descriptor List<br>This mode fetches a descriptor Set from memory that includes DMA_DSCPTR_NXT, allowing maximum flexibility in locating descriptors in memory.                                                                                                                                                                                                                                                                                                                       |
|         |          | 5<br>DSCA - Descriptor Array<br>This mode fetches a descriptor set from memory that does not include the DMA_DSCPTR_NXT element. Because the descriptor set does not contain a next descriptor pointer entry, the DMA defaults to using the DMA_DSCPTR_CUR register to step through descriptors, allowing a group of descriptors sets to follow one another in                                                                                                                                    |

| 6:4     | PSIZE    | <p>Peripheral Transfer Word Size.</p> <p>The DMA_CFG.PSIZE bits select peripheral transfer sizes as 8, 16, 32, or 64 bits wide. Each request/grant results in a single peripheral access. There is no bursting on the peripheral bus, so the DMA_CFG.PSIZE selection must be less than, or equal to, the width of the bus. If the selection is greater than the bus width, a configuration error occurs. Note that the processor's peripheral bus is dedicated to DMA and peripheral accesses.</p> |

| 3       | CADDR    | Use Current Address.<br>If the DMA_CFG.CADDR bit is cleared, the DMA loads the DMA_ADDRSTART register on the first access of the work unit. If the DMA_CFG.CADDR bit is set, the DMA uses the DMA_ADDR_CUR register value for the starting address for the work unit and writes the same value to the DMA_ADDRSTART register.<br>This operation permits continuation of a previous work unit. If this mode is used at the end of a descriptor list or array, the DMA ignores the start address value that is fetched as part of the descriptor set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                       |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Load Starting Address |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Use Current Address   |
| 2       | SYNC     | Synchronize Work Unit Transitions.<br>Setting the DMA_CFG.SYNC bit clears the DMA FIFO and pointers before starting the first Work Unit of a Work Unit Chain.<br>When the transfer direction is memory read/transmit (DMA_CFG.WNR =0), the DMA waits until all data has been transmitted to peripheral before moving on to next Work Unit, clearing the FIFO and pointers.<br>When the transfer direction is memory write/receive (DMA_CFG.WNR =1), the DMA ignores the DMA_CFG.SYNC bit value after processing the first Work Unit of a Work Unit Chain. Because the channel is allowed to receive data when turned on but idling, there could be data in the FIFO that was put in by the peripheral before the channel was programmed. With DMA_CFG.SYNC set at the beginning of a work unit chain (during the first work unit), the DMA clears the FIFO, erasing the data put in to the FIFO while the channel was idling.<br>Syncing lets you change the DMA_CFG.PSIZE between individual work units and (in some cases) work unit chains. The sync resets the pointers in the FIFO, preventing misaligned FIFO access.<br>The DMA_CFG.MSIZE may be changed between consecutive work units, independent of the DMA_CFG.SYNC bit setting.<br>Syncing also permits changes to transfer direction. And, because the data in the FIFO is eliminated, the data that went into the FIFO from one direction (transmit or receive) is not sent back in the other direction after the direction change. |                       |

|         |          | 1 Receive (Write to memory)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0       | EN       | DMA Channel Enable.<br>The DMA_CFG.EN enables the selected DMA Channel.<br>When a peripheral DMA channel is enabled, data requests from the peripheral denote DMA requests. When a channel is disabled, the DMA unit ignores the peripheral data request and passes it directly to the system event controller.<br>To avoid unexpected results, take care to enable the DMA channel before enabling the peripheral, and to disable the peripheral before disabling the DMA channel.<br>A transition of DMA_CFG.EN from 0 to 1 creates a hard reset of all internal counters and state, including the DMA_STAT register. (All other register values remain unaffected.) A transition from 1 to 0 maintains all counters and registers for the user to read and analyze. If a descriptor is loaded (see DMA_CFG.FLOW field) with DMA_CFG.EN cleared, the DMA goes to off/idle state after the descriptor load is complete. |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Inner Loop Count Start Value

For 2D DMA, the DMA\_XCNT contains the inner loop count. This value selects the number of DMA\_CFG.MSIZE size data transfers to make up the length of a row. For 1D DMA, DMA\_XCNT specifies the number of DMA\_CFG.MSIZE size data transfers for the entire work unit. The DMA\_XCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if DMA\_XCNT is 0x0 when a work unit begins.

DMA\_XCNT: Inner Loop Count Start Value - R/W

Reset = 0x0000 0000

Figure 13-7: DMA\_XCNT Register Diagram

Table 13-19: DMA\_XCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                   |
|---------|----------|-------------------------------------------|
| 31:0    | VALUE    | Work Unit Inner Loop Counter Start Value. |

Inner Loop Address Increment

The DMA\_XMOD contains a signed, two's-complement byte address increment. In 1D DMA, this increment is the stride that is applied after each DMA\_CFG.MSIZE size data transfer. The DMA\_XMOD register is read/write prior to enabling the channel, but is read-only after enabling channel.

The DMA\_XMOD value is specified in bytes, regardless of the work unit size. In 2D DMA, this increment is applied after each DMA\_CFG.MSIZE size data transfer in the inner loop, up to but not including the last DMA\_CFG.MSIZE size data transfer in each inner loop. After the last DMA\_CFG.MSIZE size data transfer in each inner loop, the DMA\_YMOD register is applied instead, including the last DMA\_CFG.MSIZE size data transfer of a work unit.

The DMA\_XMOD field may be set to 0. In this case, DMA is performed repeatedly to or from the same address. This approach can be useful for transferring data between a data register and an external memory-mapped peripheral.

DMA\_XMOD: Inner Loop Address Increment - R/W

Reset = 0x0000 0000

Figure 13-8: DMA\_XMOD Register Diagram

Table 13-20: DMA\_XMOD Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 31:0    | VALUE    | Inner Loop Address Increment in Bytes. |

Outer Loop Count Start Value (2D only)

For 2D DMA, the DMA\_YCNT contains the outer loop count. This register is not used in 1D DMA mode. The DMA\_YCNT register specifies the number of rows in the outer loop of a 2D DMA sequence. The DMA\_YCNT register is read/write prior to enabling the channel, but is read-only after enabling channel. Note that the DMA generates a configuration error if DMA\_YCNT is 0x0 when a work unit begins.

DMA\_YCNT: Outer Loop Count Start Value (2D only) - R/W

Reset = 0x0000 0000

Figure 13-9: DMA\_YCNT Register Diagram

| Bit No. | Bit Name | Description/Enumeration                     |
|---------|----------|---------------------------------------------|
| 31:0    | VALUE    | Work Unit Inner Loop Counter Current Value. |

## Outer Loop Address Increment (2D only)

The DMA\_YMOD contains a signed, two's-complement value. This byte address increment is applied after each decrement of the DMA\_YCNT\_CUR register. The value is the offset between the last word of one row and the first word of the next row. Note that DMA\_YMOD is specified in bytes, regardless of the work unit size. The DMA\_YMOD register is read/write prior to enabling the channel, but is read-only after enabling channel.

**DMA\_YMOD: Outer Loop Address Increment (2D only) - R/W**

Reset = 0x0000 0000

**Figure 13-10:** DMA\_YMOD Register Diagram

**Table 13-22:** DMA\_YMOD Register Fields

| Bit No. | Bit Name | Description/Enumeration                |
|---------|----------|----------------------------------------|
| 31:0    | VALUE    | Outer Loop Address Increment in Bytes. |

## Current Descriptor Pointer

The DMA\_DSCPTR\_CUR contains the memory address for the next descriptor to be loaded. The DMA\_DSCPTR\_CUR register is read/write prior to enabling the channel, but is read-only after enabling channel. For DMA\_CFG.FLOW mode settings that involve descriptor fetches, this register is used to read descriptors into appropriate MMRs before a work unit begins. For descriptor list mode, the DMA\_DSCPTR\_CUR is initialized from the DMA\_DSCPTR\_NXT register before fetching each descriptor set. Then, the address in the DMA\_DSCPTR\_CUR register increments as each descriptor is read in.

When the entire descriptor set has been read, the DMA\_DSCPTR\_CUR register contains this value:

DMA\_DSCPTR\_CUR = Descriptor Start Address + Descriptor Size (# of elements)

For descriptor array mode, the DMA\_DSCPTR\_CUR register, and not the DMA\_DSCPTR\_NXT register, must be programmed by MMR access before starting DMA operation.

DMA\_DSCPTR\_CUR: Current Descriptor Pointer - R/W

Reset = 0x0000 0000

Figure 13-11: DMA\_DSCPTR\_CUR Register Diagram

Table 13-23: DMA\_DSCPTR\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                 |
|---------|----------|-----------------------------------------|
| 31:0    | VALUE    | Pointer for Current Descriptor Element. |

Previous Initial Descriptor Pointer

The DMA\_DSCPTR\_PRV contains the initial descriptor pointer for the previous work unit. If DMA\_CFG.DESIDCPY is set, the DMA copies the initial descriptor pointer to DMA\_DSCPTR\_PRV after the work unit completes. Otherwise, the value is not updated.

To indicate an overrun, bit 0 of DMA\_DSCPTR\_PRV is used as a previous descriptor pointer overrun (PDPO) status bit. Due to aligned addressing combined with all descriptors being 32 bits in width, bits 0 and 1 of all descriptor pointers must be zero. Otherwise, an alignment error would occur when used for descriptor fetches. As a result, bit 1 and 0 of DMA\_DSCPTR\_PRV may be used for status. For more information, see the section on descriptor pointer capture in the DMA functional description.

DMA\_DSCPTR\_PRV: Previous Initial Descriptor Pointer - R/NW

Reset = 0x0000 0000

Figure 13-12: DMA\_DSCPTR\_PRV Register Diagram

Table 13-24: DMA\_DSCPTR\_PRV Register Fields

| Bit No. | Bit Name  | Description/Enumeration                  |
|---------|-----------|------------------------------------------|
| 31:2    | DESCPPREV | Pointer for Previous Descriptor Element. |
| 0       | PDPO      | Previous Descriptor Pointer Overrun.     |

Current Address

The DMA\_ADDR\_CUR contains the present memory transfer address for a given work unit. At the start of a work unit, the DMA\_ADDR\_CUR is loaded from the DMA\_ADDRSTART register, and DMA\_ADDR\_CUR is incremented as each transfer occurs. The DMA\_ADDR\_CUR register is read/write prior to enabling the channel, but is read-only after enabling channel.

DMA\_ADDR\_CUR: Current Address - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                 |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20      | TWAIT    | Trigger Wait Status.<br>The DMA_STAT.TWAIT indicates whether the DMA has or has not received a trigger. This bit is set until it reaches the next wait state. At that point, the bit is cleared, the DMA stops processing that work unit, and the following work unit is processed. The DMA does not distinguish between one or more triggers received. |
|         |          | 0 No trigger received                                                                                                                                                                                                                                                                                                                                   |
|         |          | 1 Trigger received                                                                                                                                                                                                                                                                                                                                      |

**Table 13-26:** DMA\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| 1       | IRQERR   | Error Interrupt.<br>The DMA_STAT . IRQERR indicates that the DMA has detected a documented rule violations during DMA programming or operation. The DMA cannot, however, flag all possible programming or operation issues to indicate errors. Programmers can use DMA_STAT . IRQERR to help determine which DMA issued the error interrupt. Note that the DMA_STAT . IRQERR is not cleared by a transition of the DMA_CFG . EN bit from 0 to 1. The DMA_STAT . IRQERR must be cleared with a write-1-to-clear operation prior to the DMA_CFG . EN transition for the fields to be reset. |                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | No Error       |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Error Occurred |
| 0       | IRQDONE  | Work Unit/Row Done Interrupt.<br>The DMA_STAT . IRQDONE indicates the DMA has detected the completion of a work unit or row (inner loop count) and has issued an interrupt. Programmers can use the DMA_STAT . IRQDONE status to help determine which DMA asserted the interrupt and to help distinguish between an interrupt caused based on the state of the work unit and an interrupt made by the peripheral. For more information, see the interrupts section of the DMA functional description.                                                                                     |                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Inactive       |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Active         |

## Current Count(1D) or intra-row XCNT (2D)

For 1D DMA, the DMA loads the DMA\_XCNT\_CUR from the DMA\_XCNT register at the beginning of each work unit. For 2D DMA, the DMA loads DMA\_XCNT\_CUR from the DMA\_XCNT register after the end of each row. The DMA decrements the value in DMA\_XCNT\_CUR each time a DMA\_CFG . MSIZE size data transfer occurs. When the count in DMA\_XCNT\_CUR expires, the work unit is complete. In 2D DMA, the DMA\_XCNT\_CUR value is 0 only when the entire transfer is complete.

DMA\_XCNT\_CUR: Current Count(1D) or intra-row XCNT (2D) - R/NW

Reset = 0x0000 0000

Figure 13-15: DMA\_XCNT\_CUR Register Diagram

Table 13-27: DMA\_XCNT\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                   |
|---------|----------|-------------------------------------------|
| 31:0    | VALUE    | Work Unit outer loop counter start value. |

Current Row Count (2D only)

For 2D DMA, the DMA loads the DMA\_YCNT\_CUR from the DMA\_YCNT register at the beginning of each 2D DMA session. The DMA\_YCNT\_CUR is not used for 1D DMA. The DMA decrements DMA\_YCNT\_CUR each time the DMA\_XCNT\_CUR expires during 2D DMA operation, signifying completion of an entire row transfer.

DMA\_YCNT\_CUR: Current Row Count (2D only) - R/NW

Reset = 0x0000 0000

Figure 13-16: DMA\_YCNT\_CUR Register Diagram

Table 13-28: DMA\_YCNT\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                     |
|---------|----------|---------------------------------------------|
| 31:0    | VALUE    | Work Unit outer loop counter current value. |

Bandwidth Limit Count

The DMA\_BWLCNT contains a count that determines how often the DMA issues memory transactions. The DMA loads the value from DMA\_BWLCNT into DMA\_BWLCNT\_CUR and decrements the current value each SCLK cycle. When DMA\_BWLCNT\_CUR reaches 0x0000, the next request is issued, and the DMA reloads DMA\_BWLCNT\_CUR. This bandwidth limit functionality is not applied to descriptor fetch requests. Programming 0x0000 allows the DMA to request as often as possible. 0xFFFF is a special case and causes requests to stop.

DMA\_BWLCNT: Bandwidth Limit Count - R/W

Reset = 0x0000 0000

Figure 13-17: DMA\_BWLCNT Register Diagram

Table 13-29: DMA\_BWLCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | Bandwidth Limit Count.  |

Bandwidth Limit Count Current

The DMA\_BWLCNT\_CUR contains the number of SCLK count cycles remaining before the next request is issued.

**DMA\_BWLCNT\_CUR: Bandwidth Limit Count Current - R/NW**

Reset = 0x0000 0000

**Figure 13-18:** DMA\_BWLCNT\_CUR Register Diagram

**Table 13-30:** DMA\_BWLCNT\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration        |
|---------|----------|--------------------------------|
| 15:0    | VALUE    | Bandwidth Limit Count Current. |

## Bandwidth Monitor Count

The DMA\_BWMCNT contains the maximum number of SCLK cycles allowed for a work unit to complete. Each time the DMA\_CFG register is written (MMR access only), a work unit ends, or an autobuffer wraps, the DMA loads the value in DMA\_BWMCNT into DMA\_BWMCNT\_CUR. The DMA decrements DMA\_BWMCNT\_CUR every SCLK a work unit is active. If DMA\_BWMCNT\_CUR reaches 0x0000\_0000, the DMA\_STAT . IRQERR bit is set, and the DMA\_STAT . ERRRC is set to 0x6. The DMA\_BWMCNT\_CUR remains at 0x0000\_0000 until it is reloaded when the work unit completes. Unlike other error causes, a bandwidth monitor error does not stop work unit processing. Programming 0x0000\_0000 disables bandwidth monitor functionality.

**DMA\_BWMCNT: Bandwidth Monitor Count - R/W**

Reset = 0x0000 0000

**Figure 13-19:** DMA\_BWMCNT Register Diagram

**Table 13-31:** DMA\_BWMCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 31:0    | VALUE    | Bandwidth Monitor Count. |

## Bandwidth Monitor Count Current

The DMA\_BWMCNT\_CUR contains the number of cycles remaining for the current descriptor to complete.

**DMA\_BWMCNT\_CUR: Bandwidth Monitor Count Current - R/NW**

Reset = 0x0000 0000

**Figure 13-20:** DMA\_BWMCNT\_CUR Register Diagram

**Table 13-32:** DMA\_BWMCNT\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration          |
|---------|----------|----------------------------------|
| 31:0    | VALUE    | Bandwidth Monitor Count Current. |

## DMA Channel List for ADSP-BF60x

The following tables provide DMA channel assignment and channel parametric information for the ADSP-BF60x processors.

**Table 13-33:** SPORT DMA Channels

| DMA Channel | Peripheral       | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA0        | SPORT0 Channel A | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-33:** SPORT DMA Channels (Continued)

| DMA Channel | Peripheral       | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA1        | SPORT0 Channel B | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA2        | SPORT1 Channel A | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA3        | SPORT1 Channel B | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA4        | SPORT2 Channel A | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA5        | SPORT2 Channel B | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-34:** SPI DMA Channels

| DMA Channel | Peripheral    | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|---------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA6        | SPI0 Transmit | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA7        | SPI0 Receive  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA8        | SPI1 Transmit | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA9        | SPI1 Receive  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-35:** RSI DMA Channels

| DMA Channel | Peripheral | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA10       | RSI0       | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-36:** SDU DMA Channels

| DMA Channel | Peripheral | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA11       | SDU0       | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-37:** Link Port DMA Channels

| DMA Channel | Peripheral | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA13       | Linkport0  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA14       | Linkport1  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA15       | Linkport2  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |
| DMA16       | Linkport3  | 64                 | No                               | 32 bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-38:** UART DMA Channels

| DMA Channel | Peripheral     | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|----------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA17       | UART0 Transmit | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA18       | UART0 Receive  | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA19       | UART1 Transmit | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |
| DMA20       | UART1 Receive  | 64                 | No                               | 32-bit                             | 32-bit                                 | 4                     | 4                      |

**Table 13-39:** MDMA Channels

| DMA Channel | Peripheral                | FIFO Depth (Bytes) | Bandwidth Limit/Monit or Support | Memory Bus Width (DMA_STAT .MSIZE) | Peripheral Bus Width (DMA_STAT .PSIZE) | Max Outstanding Reads | Max Outstanding Writes |
|-------------|---------------------------|--------------------|----------------------------------|------------------------------------|----------------------------------------|-----------------------|------------------------|
| DMA21       | MDMA0 Source/ Destination | 128                | Yes                              | 32-bit                             | 32-bit                                 | 8                     | 7                      |
| DMA22       | MDMA0 Destination/Source  | 64                 | Yes                              | 32-bit                             | 32-bit                                 | 8                     | 4                      |
| DMA23       | MDMA1 Source/ Destination | 64                 | Yes                              | 32-bit                             | 32-bit                                 | 8                     | 4                      |
| DMA24       | MDMA1 Destination/Source  | 64                 | Yes                              | 32-bit                             | 32-bit                                 | 8                     | 4                      |

**Table 13-39:** MDMA Channels (Continued)

| <b>DMA Channel</b> | <b>Peripheral</b>        | <b>FIFO Depth (Bytes)</b> | <b>Bandwidth Limit/Monitor or Support</b> | <b>Memory Bus Width (DMA_STAT.MSIZE)</b> | <b>Peripheral Bus Width (DMA_STAT.PSIZE)</b> | <b>Max Outstanding Reads</b> | <b>Max Outstanding Writes</b> |
|--------------------|--------------------------|---------------------------|-------------------------------------------|------------------------------------------|----------------------------------------------|------------------------------|-------------------------------|
| DMA25              | MDMA2 Source/Destination | 128                       | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 7                             |
| DMA26              | MDMA2 Destination/Source | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |
| DMA27              | MDMA3 Source/Destination | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |
| DMA28              | MDMA3 Destination/Source | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |

**Table 13-40:** CRC DMA Channels

| <b>DMA Channel</b> | <b>Peripheral</b> | <b>FIFO Depth (Bytes)</b> | <b>Bandwidth Limit/Monitor or Support</b> | <b>Memory Bus Width (DMA_STAT.MSIZE)</b> | <b>Peripheral Bus Width (DMA_STAT.PSIZE)</b> | <b>Max Outstanding Reads</b> | <b>Max Outstanding Writes</b> |
|--------------------|-------------------|---------------------------|-------------------------------------------|------------------------------------------|----------------------------------------------|------------------------------|-------------------------------|
| DMA21              | CRC0 Receive      | 128                       | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 7                             |
| DMA22              | CRC0 Transmit     | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |
| DMA23              | CRC1 Receive      | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |
| DMA24              | CRC1 Transmit     | 64                        | Yes                                       | 32-bit                                   | 32-bit                                       | 8                            | 4                             |

**Table 13-41:** EPPI DMA Channels

| <b>DMA Channel</b> | <b>Peripheral</b>          | <b>FIFO Depth (Bytes)</b> | <b>Bandwidth Limit/Monitor Support</b> | <b>Memory Bus Width (DMA_STAT.MSIZE)</b> | <b>Peripheral Bus Width (DMA_STAT.PSIZE)</b> | <b>Max Outstanding Reads</b> | <b>Max Outstanding Writes</b> |
|--------------------|----------------------------|---------------------------|----------------------------------------|------------------------------------------|----------------------------------------------|------------------------------|-------------------------------|
| DMA29              | EPPI0 Luma/Pixel Pipe Data | 128                       | No                                     | 32-bit                                   | 32-bit                                       | 8                            | 7                             |

# 14 General-Purpose Ports (PORT)

This section describes general-purpose ports, pin multiplexing, general-purpose input/output (GPIO) functionality, and pin interrupts.

The general-purpose ports provide the following three functions.

- Pin multiplexing scheme
- GPIO functionality
- Pin interrupts

**Figure 14-1:** Simplified GPIO and Pin Interrupt Signal Flow

## PORT Features

The PORTs include the following features:

- Up to 112 general-purpose I/O (GPIO) pins
- Input mode, output mode, and open-drain mode of GPIO operation
- Port multiplexing controlled by individual pin-per-pin base
- No glue hardware required for unused pins
- Six interrupt channels dedicated to pin interrupts
- All port pins provide interrupt functionality
- Byte-wide pin-to-interrupt assignment

## PORT Functional Description

Every port pin can operate in GPIO mode. This is the default after reset and is controlled by the port-specific `PORTx_FER` enable register. Every port has a dedicated set of MMR registers that control the GPIO functionality. Every bit in these registers represents a certain GPIO pin of the specific port.

By default, every GPIO is set to input mode. The input drivers are not enabled, which avoids the need for unnecessary current sinks and the external pulling of resistors on unused or *do not care* pins.

### Input Mode

The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable any GPIO input drivers, set the corresponding bits in the input enable register `PORTx_INEN`. When enabled, a read from the `PORTx` register returns the logical state of the input pin. The input signal does not overwrite the state of the flip-flop used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the `PORTx` register can alter the state of the flip-flop, but the change cannot be read back.

### Output Mode

Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the direction registers. Direction registers are implemented as a pair of write-1-to-set (W1S) and write-1-to-clear (W1C) MMRs, called `PORTx_DIR_SET` and `PORTx_DIR_CLEAR`. This way, the direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port.

Both `PORTx_DIR_SET` and `PORTx_DIR_CLEAR` registers return the same value when read and a logical 1 indicates an enabled output. The state of output pins is controlled by the `PORTx` registers. A logical 0 drives the output low while a logical 1 drives the output high.

While the `PORTx` register can be written to alter all GPIOs of a specific port at once, there is also a pair of `W1S` and `W1C` MMRs, called `PORTx_SET` and `PORTx_CLEAR` that enable manipulation of individual GPIO outputs. The state of the outputs can be obtained by reading the `PORTx` registers. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the flip-flop to avoid any volatile levels on the output.

## Open-Drain Mode

Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the `PORTx` or `PORTx_CLEAR` register then set the one bit in the `PORTx_INEN` register. Read from the `PORTx` register then return the status from the pin and do not return the state of the internal flip-flop.

By toggling the output driver through the `PORTx_DIR_SET` and `PORTx_DIR_CLEAR` register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set. When a GPIO port is used in open-drain mode, care must be taken not to exceed the  $V_{IH}$  operating condition associated with the respective pins.

## PORT Register List

Every port pin can operate in general-purpose I/O (GPIO) mode. This operation is the default after processor reset and is controlled by a set of registers that control GPIO functionality. Every bit in these registers represents a certain GPIO pin of a specific port. For more information on PORT functionality, see the PORT register descriptions.

**Table 14-1:** PORT Module Registers

| Name                       | Description                           |
|----------------------------|---------------------------------------|
| <code>PORT_FER</code>      | Port x Function Enable Register       |
| <code>PORT_FER_SET</code>  | Port x Function Enable Set Register   |
| <code>PORT_FER_CLR</code>  | Port x Function Enable Clear Register |
| <code>PORT_DATA</code>     | Port x GPIO Data Register             |
| <code>PORT_DATA_SET</code> | Port x GPIO Data Set Register         |
| <code>PORT_DATA_CLR</code> | Port x GPIO Data Clear Register       |

**Table 14-1:** PORT Module Registers (Continued)

| Name          | Description                                |
|---------------|--------------------------------------------|
| PORT_DIR      | Port x GPIO Direction Register             |
| PORT_DIR_SET  | Port x GPIO Direction Set Register         |
| PORT_DIR_CLR  | Port x GPIO Direction Clear Register       |
| PORT_INEN     | Port x GPIO Input Enable Register          |
| PORT_INEN_SET | Port x GPIO Input Enable Set Register      |
| PORT_INEN_CLR | Port x GPIO Input Enable Clear Register    |
| PORT_MUX      | Port x Multiplexer Control Register        |
| PORT_DATA_TGL | Port x GPIO Input Enable Toggle Register   |
| PORT_POL      | Port x GPIO Polarity Invert Register       |
| PORT_POL_SET  | Port x GPIO Polarity Invert Set Register   |
| PORT_POL_CLR  | Port x GPIO Polarity Invert Clear Register |
| PORT_LOCK     | Port x GPIO Lock Register                  |
| PORT_REVID    | Port x GPIO Revision ID                    |

## ADSP-BF60x PORT Muxing Table

## PINT Register List

The pin-interrupt assignment (PINT) module controls the pin-to-interrupt assignment in a byte-wide manner. The pin-interrupt assignment registers do not consist of 32 individual bits. They consist of four control bytes, each functioning as a multiplexer control.

All PINT registers are 32 bits wide and can be accessed by 32-bit load/store instructions. They also support 16-bit operation where the upper 16 bits are ignored and the application uses the lower 16 bits only. Consequently, all PINT registers support 32-bit accesses as well as 16-bit accesses for the lower half words. Applications may use faster 16-bit accesses as long as they do not require functionality of upper register halves.

**Table 14-9:** PINT Module Registers

| Name          | Description              |
|---------------|--------------------------|
| PINT_MSK_SET  | Pint Mask Set Register   |
| PINT_MSK_CLR  | Pint Mask Clear Register |
| PINT_REQ      | Pint Request Register    |
| PINT_ASSIGN   | Pint Assign Register     |
| PINT_EDGE_SET | Pint Edge Set Register   |

**Table 14-9:** PINT Module Registers (Continued)

| Name          | Description                |
|---------------|----------------------------|
| PINT_EDGE_CLR | Pint Edge Clear Register   |
| PINT_INV_SET  | Pint Invert Set Register   |
| PINT_INV_CLR  | Pint Invert Clear Register |
| PINT_PINSTATE | Pint Pinstate Register     |
| PINT_LATCH    | Pint Latch Register        |

## ADSP-BF60x PINT Interrupt List

**Table 14-10:** ADSP-BF60x PINT Interrupt List

| Description               | ID | DMA Channel | Sensitivity |

## PORT Definitions

This section provides definitions relating to the GPIO ports.

### *x* (*PORTx*)

The naming convention for bits uses a lowercase "x" to represent one of the existing ports alphabetically named beginning with A,B,C,... For example, the name `PORTx_REG` represents any one or all of `PORTA_REG`, `PORTB_REG`, `PORTC_REG`, and so on. The bit name `Px0` represents `PA0`, `PB0`, and so on.

## PORT Architectural Concepts

This section describes architectural concepts relating to the GPIO ports and signals, including external and internal interfaces.

## External Interfaces

The pin multiplexing hardware can be seen as a layer between the on-chip peripherals and the pads of the silicon. All port groups are controlled by this unit.

## Internal Interfaces

All MMR registers of the pin multiplexing, GPIO and pin interrupt control blocks can be accessed through the MMR bus. There is no DMA support. Every one of the pin interrupt modules has its own and dedicated interrupt request output signal that connects directly to the SIC controller.

## PORT Event Control

The following sections describe event generation in the PORT module.

## PORT Interrupt Signals

The pin interrupts are completely decoupled from GPIO functionality which has the following advantages.

- Flexible mapping scheme enables pins from up to four different ports to be grouped into one common interrupt scheme.
- Interrupts work on input and output pins regardless of whether in GPIO or functional mode.

The ADSP-BF60x Blackfin processors have a number of interrupt channels dedicated to pin interrupts. These channels are managed by a set of hardware blocks named PINT<sub>x</sub> (PINT0–PINT5). Every PINT<sub>x</sub> block can sense up to 32 GPIO pins as described in the following list and shown in the figure below.

- PINT0 can sense pins of PORTA and PORTB
- PINT1 can sense pins of PORTB and PORTC
- PINT2 can sense pins from PORTC and PORTD
- PINT3 can sense pins from PORTD and PORTE
- PINT4 can sense pins from PORTE and PORTF
- PINT5 can sense pins from PORTF and PORTG

Both 32-bit and 16-bit peripheral bus accesses to PINT<sub>x</sub> registers are supported.

**Figure 14-2:** GPIO to PINT<sub>x</sub> Assignment

Pins are connected to the PINTx module and then to the system event controller. Special attention is required with regard to how the pins are assigned to the PINTx modules as shown in the PINTx block diagram below.

**Figure 14-3:** PINTx Block Diagram

The ports are subdivided into 8-bit half ports, with lower and upper half 8-bit units. The `PINTx_ASSIGN` registers control the 8-bit multiplexers shown in the Block Diagram. Lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINTx block. Upper half units can be forwarded to either byte 1 or byte 3 of the pin interrupts blocks, without further restrictions.

When a half port is assigned to a byte in any PINTx block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the `PINTx_PINSTATE` register. When neither input nor output drivers of the pin are enabled, the pin state is read as zero. The `PINTx_PINSTATE` register reports the inverted state of the pin if the signal inverter is activated by the `PINTx_INVERT_SET` register. The inverter can be enabled on a individual bit by bit basis. Every bit in the `PINTx_INVERT_SET/PINTx_INVERT_CLEAR` register pair represents a pin signal.

An interrupt can be generated on an active high level of the signal or a raising edge of the signal. The default behavior is level sensitivity. The `PINTx_EDGE_SET` register can be used to change the behavior to edge sensitivity. By enabling the inverter using the `PINTx_INVERT_SET` register, the interrupt behavior can be altered to trigger on active-low signals or falling edges.

The PINTx modules also assist if both signals are required to generate interrupts. If two different interrupt requests are required, the `PINTx_ASSIGN` registers can route a signal to two different PINTx blocks, where one block inverts the signal and the other one does not. If both signal edges can report over the same interrupt, every signal can be routed through to different bit positions within a single PINTx block, where the inverted signal should be enabled for either one. The servicing software routine can then tell from the `PINTx_LATCH` register whether a falling, a rising, or both edges have occurred.

Regardless of whether using level-sensitive or edge-sensitive mode, an interrupt is always latched by the hardware. Latched signals can be read from the `PINTx_LATCH` registers. Latches can only be cleared by a software or a hardware reset. To clear, W1C the `PINTx_REQUEST` or the `PINTx_LATCH` register. If the pin

state does not change by the time the interrupt service routine returns, the interrupt is requested again when in level-sensitive mode.

Because every PINTx block groups up to 32 pin signals, the PINTx\_MASK\_SET/PINTx\_INVERT\_CLEAR register pair can control which of the signals can request an interrupt at the system level. Software may interrogate the PINTx\_REQUEST register for signaling pins. The PINTx\_REQUEST bits represent a logical AND between the mask and the latch. When any of these bits is set, an interrupt is forwarded to the SIC controller.

All MMR registers in the pin interrupt module are 32 bits wide. Individual bits of the PINTx registers represent the associated pins. Nevertheless, the 32 bits can also be seen as four groups of eight pins. Each group can manage up to eight pins out of either the lower or an upper half of any associated port.

## PORT Programming Model

The following sections description of the overall program model of the general purpose ports.

*GPIO Programming Model Flow (Part 1)*, *GPIO Programming Model Flow (Part 2)*, and *GPIO Programming Model Flow (Part 3)* show the programming model of the general-purpose ports. This includes the GPIO input and output operation, open-drain mode, and the pin interrupt PINTx modules.

**Figure 14-4:** GPIO Programming Model Flow (Part 1)

\*The pin polarity set at this point will effect the behavior of the interrupt function described in the next figure. If the invert bit si set for a given pin, and edge sensitive interrupts are configured. The interrupt is latched on detection of a falling edge. If the inverse bit is clear, edge sensitive interrupts are generated on the rising edge. For level sensitive interrupts, enabling the inverter results in interrupts being detected on a low signal. Disabling the inverter results in interrupts being latched on high signals.

\*\*Open-drain mode assumes an external pull-up resistor is fitted.

## PORT Register Descriptions

General Purpose Input/Output (PORT) contains the following registers.

**Table 14-13:** PORT Module Registers

| Name         | Description                         |
|--------------|-------------------------------------|
| PORT_FER     | Port x Function Enable Register     |
| PORT_FER_SET | Port x Function Enable Set Register |

**Table 14-13:** PORT Module Registers (Continued)

| Name          | Description                                |
|---------------|--------------------------------------------|
| PORT_FER_CLR  | Port x Function Enable Clear Register      |
| PORT_DATA     | Port x GPIO Data Register                  |
| PORT_DATA_SET | Port x GPIO Data Set Register              |
| PORT_DATA_CLR | Port x GPIO Data Clear Register            |
| PORT_DIR      | Port x GPIO Direction Register             |
| PORT_DIR_SET  | Port x GPIO Direction Set Register         |
| PORT_DIR_CLR  | Port x GPIO Direction Clear Register       |
| PORT_INEN     | Port x GPIO Input Enable Register          |
| PORT_INEN_SET | Port x GPIO Input Enable Set Register      |
| PORT_INEN_CLR | Port x GPIO Input Enable Clear Register    |
| PORT_MUX      | Port x Multiplexer Control Register        |
| PORT_DATA_TGL | Port x GPIO Input Enable Toggle Register   |
| PORT_POL      | Port x GPIO Polarity Invert Register       |
| PORT_POL_SET  | Port x GPIO Polarity Invert Set Register   |
| PORT_POL_CLR  | Port x GPIO Polarity Invert Clear Register |
| PORT_LOCK     | Port x GPIO Lock Register                  |
| PORT_REVID    | Port x GPIO Revision ID                    |

## Port x Function Enable Register

The `PORT_FER` register bits indicate each port bit's operating mode: general purpose I/O mode or peripheral mode. After reset, all pins default to GPIO mode. Setting a bit in the `PORT_FER` registers enables a peripheral module to take ownership of the pin. The function enable bits impact output control only. Regardless of the setting of the function enable bits, both GPIO and peripherals can still sense the pin input. After a function is enabled, it is up to the `PORT_MUX` registers as to which peripheral takes control.

**PORT\_FER: Port x Function Enable Register - R/W**

Reset = 0x0000 0000

**Figure 14-7: PORT\_FER Register Diagram**

**Table 14-14: PORT\_FER Register Fields**

| Bit No. | Bit Name | Description/Enumeration |                 |

| 0       | PX0      | Port x Bit 0 Mode.      |                 |
|         |          | 0                       | GPIO Mode       |
|         |          | 1                       | Peripheral Mode |

## Port x Function Enable Set Register

The PORT\_FER\_SET register permits enabling peripheral mode for each bit and corresponding GPIO pin. Writing 1 to a bit in PORT\_FER\_SET enables peripheral mode for the corresponding pin.

PORT\_FER\_SET: Port x Function Enable Set Register - R/W

Reset = 0x0000 0000

|         |          | 1 Set Bit for Peripheral Mode |

## Port x Function Enable Clear Register

The PORT\_FER\_CLR register permits enabling GPIO mode for each bit and corresponding GPIO pin. Writing 1 to a bit in PORT\_FER\_CLR enables GPIO mode for the corresponding pin.

### PORT\_FER\_CLR: Port x Function Enable Clear Register - R/W

Reset = 0x0000 0000

## Port x GPIO Data Register

The `PORT_DATA` register operates differently for port bits/pins, depending on whether the bit/pin is in output mode or input mode. In both modes, a set bit in the `PORT_DATA` register corresponds to a signal high on a GPIO pin, and a cleared bit in the `PORT_DATA` register corresponds to a signal low on a GPIO pin.

The `PORT_DATA`, `PORT_DATA_SET`, and `PORT_DATA_CLR` registers control the state of GPIO pins in output mode. To enable output mode (and output drivers), use the `PORT_DIR_SET` and `PORT_DIR_CLR` registers.

Writes to the `PORT_DATA` register affect the state of all pins of the port that are in output mode. To set or clear specific pins without impacting other pins of the port, use the `PORT_DATA_SET` and `PORT_DATA_CLR` registers.

When the GPIO pins are in input mode (input driver is enabled with the `PORT_INEN` register), reads from the `PORT_DATA`, `PORT_DATA_SET`, and `PORT_DATA_CLR` registers return the state of the respective GPIO pins.

Note that when the input driver is not enabled, reads from the `PORT_DATA`, `PORT_DATA_SET`, and `PORT_DATA_CLR` registers return the value previously written to the registers.

## Port x GPIO Data Clear Register

The PORT\_DATA\_CLR register operates differently for port bits/pins, depending on whether the bit/pin is output mode or input mode. For more information, see the PORT\_DATA register description.

PORT\_DATA\_CLR: Port x GPIO Data Clear Register - R/W

Reset = 0x0000 0000

|         |          | 0                        | No Effect<br>Write 0 has no effect in output mode.  |
|         |          | 1                        | Clear Bit<br>Write 1 for signal low in output mode. |

## Port x GPIO Direction Register

The `PORT_DIR`, `PORT_DIR_SET`, and `PORT_DIR_CLR` registers select output or input mode for GPIO pins and enable output drivers. Use the `PORT_INEN`, `PORT_INEN_SET`, and `PORT_INEN_CLR` registers to enable or disable input drivers.

Writes to the `PORT_DIR` register affect the state of all pins of the port. To select direction for specific pins without impacting other pins of the port, use the `PORT_DIR_SET` and `PORT_DIR_CLR` registers.

Setting a bit in the `PORT_DIR` register enables output mode on the corresponding a GPIO pin, and a clearing a bit in the `PORT_DIR` register disables output mode on the corresponding GPIO pin.

**Input Mode** - The default mode of every GPIO pin after reset is input mode, but the input drivers are not enabled. To enable any GPIO input drivers, set the corresponding bits in `PORT_INEN` register. When enabled, a read from the `PORT_DATA` register returns the logical state of the input pin. The input signal does not overwrite the state of the bit used for the output case. That state can only be altered by software. If the input driver is enabled, a write to the `PORT_DATA` register can alter the state of the bit, but the change cannot be read back.

**Output Mode** - Any GPIO pin can be configured for output mode. The GPIO output drivers are enabled by setting the corresponding bits in the `PORT_DIR`, `PORT_DIR_SET`, or `PORT_DIR_CLR` registers. By using the `PORT_DIR_SET` and `PORT_DIR_CLR` registers, direction of the signal flow of individual GPIO pins can be altered by separate software threads without mutually impacting other GPIOs on the same port. Both registers return the same value when read. Because the state of the GPIO output can already be controlled before the output driver is enabled, it is recommended to first set or clear the bit (using the `PORT_DATA`, `PORT_DATA_SET`, or `PORT_DATA_CLR` registers) to avoid any volatile levels on the output.

**Open-Drain Mode**- Every GPIO can also be used in open-drain mode. To accomplish this, first, clear the respective bit in the `PORT_DATA` or `PORT_DATA_CLR` register then set the one bit in the `PORT_INEN` register. Reads from the `PORT_DATA` register then return the status from the pin and do not return the state of the internal flip-flop. By toggling the output driver through the `PORT_DIR_SET` and `PORT_DIR_CLR` register pair, the output signal can be pulled low or three-stated as required. Note that the polarity of the driven signal can be inverted when the internal flip-flop is set instead. When a GPIO port is used in open-drain mode, care must be taken not to exceed the  $V_{IH}$  operating condition associated with the respective pin.

**PORT\_DIR: Port x GPIO Direction Register - R/W**

## Port x GPIO Input Enable Register

The `PORT_INEN`, `PORT_INEN_SET`, and `PORT_INEN_CLR` registers enable or disable input drivers, which are required for using a GPIO pin in input mode.

Writes to the `PORT_INEN` register affect the input drivers for all pins of the port. To set or clear specific pin drivers without impacting other pin drivers of the port, use the `PORT_INEN_SET` and `PORT_INEN_CLR` registers.

If the input is enabled, reads from the `PORT_DATA`, `PORT_DATA_SET`, or `PORT_DATA_CLR` registers return the state of the pins. However, the state of the output is not overwritten by the input. It is altered by software writes only. Input and output drivers can be enabled at the same time. In this case, a read of the data register returns the true value of the data register and not the pin state.

For more information see the `PORT_DATA` register description and the `PORT_DIR` register description.

## Port x Multiplexer Control Register

When a pin is in peripheral mode (not GPIO mode), the `PORT_MUX` register controls which peripheral takes ownership of a pin. Ports may have multiple, different peripheral functions. Two bits are required to describe every multiplexer on an individual pin-by-pin scheme. For example, Bit 0 and Bit 1 of the `PORT_MUX` register control the multiplexer of Pin 0, Bit 2 and Bit 3 of `PORT_MUX` control the multiplexer of Pin 1, and so on. The value of any `PORT_MUX` bit has no effect on the port pins when the associated bit in the `PORT_FER` register is 0 (selects GPIO mode). Even if a port has only one function, the `PORT_MUX` register is still present. For single function ports (no multiplexing is needed), leave the `PORT_MUX` bits at 0 (default). For all `PORT_MUX` bit fields: 00 = default/reset peripheral option, 01 = first alternate peripheral option, 10 = second alternate peripheral option, and 11 = third alternate peripheral option.

## Port x GPIO Input Enable Toggle Register

The PORT\_DATA\_TGL register permits toggling the state of output GPIO pins. Setting bits in the PORT\_DATA\_TGL register affects the state of specific pins without impacting other pins of the port.

Reading the PORT\_DATA\_TGL returns the state of the PORT\_DATA register output pin state, but does not return the input pin/signal state.

PORT\_DATA\_TGL: Port x GPIO Input Enable Toggle Register - R/W

## Port x GPIO Polarity Invert Register

The `PORT_POL`, `PORT_POL_SET`, and `PORT_POL_CLR` registers enable or disable inverting polarity of GPIO signals. To invert polarity of peripheral signals, use the inversion selection programming in the signal's corresponding module.

Writes to the `PORT_POL` register affect the polarity inversion selection of all pins of the port. To enable or disable polarity inversion for specific pins without impacting other pins of the port, use the `PORT_POL_SET` and `PORT_POL_CLR` registers.

Setting a bit in the `PORT_POL` register enables polarity inversion on the corresponding inversion GPIO pin, making the pin active-low or falling-edge sensitive. Clearing a bit in the `PORT_POL` register disables polarity (default state) on the corresponding GPIO pin, making it active-high or rising-edge sensitive.

## Port x GPIO Polarity Invert Set Register

The PORT\_POL\_SET register enables polarity inversion for GPIO pins. For more information, see the PORT\_POL register description.

PORT\_POL\_SET: Port x GPIO Polarity Invert Set Register - R/W

Reset = 0x0000 0000

|         |          | 1                                 | Set Bit<br>Set to enable GPIO pin polarity invert. |

## Port x GPIO Polarity Invert Clear Register

The PORT\_POL\_CLR register disables polarity inversion for GPIO pins. For more information, see the PORT\_POL register description.

PORT\_POL\_CLR: Port x GPIO Polarity Invert Clear Register - R/W

Reset = 0x0000 0000

## Port x GPIO Lock Register

The `PORT_LOCK` register enables (unlocks) or disables (locks) write access selectively for the PORT control registers.

### PORT\_LOCK: Port x GPIO Lock Register - R/W

Reset = 0x0000 0000

**Figure 14-24:** PORT\_LOCK Register Diagram

**Table 14-31:** PORT\_LOCK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | LOCK     | Lock.<br>If the global lock bit is set (SPU_CTL_GLCK bit =1) and the PORT_LOCK.LOCK bit is set, the PORT_LOCK register is read only (locked). |
|         |          | 0                      Unlock                                                                                                                 |
|         |          | 1                      Lock                                                                                                                   |
| 5       | POLAR    | Polarity Lock.<br>The PORT_LOCK.POLAR disables write access to the PORT_POL, PORT_POL_SET, and PORT_POL_CLR registers.                        |
|         |          | 0                      Unlock POL                                                                                                             |
|         |          | 1                      Lock POL                                                                                                               |
| 4       | INEN     | Input Enable Lock.<br>The PORT_LOCK.INEN disables write access to the PORT_INEN, PORT_INEN_SET, and PORT_INEN_CLR registers.                  |
|         |          | 0                      Unlock INEN                                                                                                            |
|         |          | 1                      Lock INEN                                                                                                              |
| 3       | DIR      | Direction Lock.<br>The PORT_LOCK.DIR disables write access to the PORT_DIR, PORT_DIR_SET, PORT_DIR_CLR registers.                             |
|         |          | 0                      Lock DIR                                                                                                               |
|         |          | 1                      Unlock DIR                                                                                                             |
| 2       | DATA     | Data Lock.<br>The PORT_LOCK.DATA disables write access to the PORT_DATA, PORT_DATA_SET, PORT_DATA_CLR, and PORT_DATA_TGL registers.           |
|         |          | 0                      Unlock DATA                                                                                                            |
|         |          | 1                      Lock DATA                                                                                                              |

**Table 14-31:** PORT\_LOCK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                     |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------|
| 1       | MUX      | Function Multiplexer Lock.<br>The PORT_LOCK.MUX disables write accesses to the PORT_MUX register.                           |
|         |          | 0                      Unlock MUX                                                                                           |
|         |          | 1                      Lock MUX                                                                                             |
| 0       | FER      | Function Enable Lock.<br>The PORT_LOCK.FER disables write access to the PORT_FER, PORT_FER_SET, and PORT_FER_CLR registers. |
|         |          | 0                      Unlock FER                                                                                           |
|         |          | 1                      Lock FER                                                                                             |

Port x GPIO Revision ID

The PORT\_REVID register provides the PORT module revision information.

**PORT\_REVID: Port x GPIO Revision ID - R/WE**

Reset = 0x0000 0000

**Figure 14-25:** PORT\_REVID Register Diagram

**Table 14-32:** PORT\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:4     | MAJOR    | Major ID.               |
| 3:0     | REV      | Revision ID.            |

## PINT Register Descriptions

PINT (PINT) contains the following registers.

**Table 14-33:** PINT Module Registers

| Name          | Description                |
|---------------|----------------------------|
| PINT_MSK_SET  | Pint Mask Set Register     |
| PINT_MSK_CLR  | Pint Mask Clear Register   |
| PINT_REQ      | Pint Request Register      |
| PINT_ASSIGN   | Pint Assign Register       |
| PINT_EDGE_SET | Pint Edge Set Register     |
| PINT_EDGE_CLR | Pint Edge Clear Register   |
| PINT_INV_SET  | Pint Invert Set Register   |
| PINT_INV_CLR  | Pint Invert Clear Register |
| PINT_PINSTATE | Pint Pinstate Register     |
| PINT_LATCH    | Pint Latch Register        |

### Pint Mask Set Register

The PINT\_MSK\_SET register permits unmasking (enabling) of interrupts. Writing 1 to a bit in PINT\_MSK\_SET unmask the corresponding pin interrupt.

**PINT\_MSK\_SET: Pint Mask Set Register - R/W**

Reset = 0x0000 0000

**Figure 14-26: PINT\_MSK\_SET Register Diagram**

**Table 14-34:** PINT\_MSK\_SET Register Fields

| Bit No. | Bit Name | Description/Enumeration                              |
|---------|----------|------------------------------------------------------|
| 31      | PIQ31    | Pin Interrupt 31 Unmask.<br>Set to enable interrupt. |
| 30      | PIQ30    | Pin Interrupt 30 Unmask.<br>Set to enable interrupt. |

**Table 14-34:** PINT\_MSK\_SET Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                             |
|---------|----------|-----------------------------------------------------|
| 3       | PIQ3     | Pin Interrupt 3 Unmask.<br>Set to enable interrupt. |
| 2       | PIQ2     | Pin Interrupt 2 Unmask.<br>Set to enable interrupt. |
| 1       | PIQ1     | Pin Interrupt 1 Unmask.<br>Set to enable interrupt. |
| 0       | PIQ0     | Pin Interrupt 0 Unmask.<br>Set to enable interrupt. |

## Pint Mask Clear Register

The PINT\_MSK\_CLR register permits masking (disabling) of interrupts. Writing 1 to a bit in PINT\_MSK\_CLR masks the corresponding pin interrupt.

**PINT\_MSK\_CLR: Pint Mask Clear Register - R/W**

Reset = 0x0000 0000

**Figure 14-27: PINT\_MSK\_CLR Register Diagram**

**Table 14-35:** PINT\_MSK\_CLR Register Fields

| Bit No. | Bit Name | Description/Enumeration                             |
|---------|----------|-----------------------------------------------------|
| 31      | PIQ31    | Pin Interrupt 31 Mask.<br>Set to disable interrupt. |
| 30      | PIQ30    | Pin Interrupt 30 Mask.<br>Set to disable interrupt. |

| 1       | PIQ1     | Pin Interrupt 1 Mask.<br>Set to disable interrupt. |
| 0       | PIQ0     | Pin Interrupt 0 Mask.<br>Set to disable interrupt. |

## Pint Request Register

The `PINT_REQ` register indicates interrupt request status for pin interrupts. When set, an interrupt request is pending. When cleared, there is no interrupt request pending.

Both the `PINT_REQ` and `PINT_LATCH` registers indicate whether an interrupt request is latched on the respective pin. The `PINT_LATCH` register is a latch that operates regardless of the interrupt masks. Bits of the `PINT_REQ` register depend on the mask register. The `PINT_REQ` register is a logical AND of the `PINT_LATCH` register and the interrupt mask.

PINT\_REQ: Pint Request Register - R/W

Reset = 0x0000 0000

Figure 14-28: PINT\_REQ Register Diagram

**Table 14-36:** PINT\_REQ Register Fields

| Bit No. | Bit Name | Description/Enumeration                               |
|---------|----------|-------------------------------------------------------|
| 31      | PIQ31    | Pin Interrupt 31 Request.<br>If set, request pending. |
| 30      | PIQ30    | Pin Interrupt 30 Request.<br>If set, request pending. |
| 29      | PIQ29    | Pin Interrupt 29 Request.<br>If set, request pending. |

Pint Assign Register

The PINT\_ASSIGN register controls the pin-to-interrupt assignment in a byte-wide manner. This register consists of four control bytes that each function as a multiplexer control.

The PINT ports are subdivided into 8-bit half ports, resulting in lower and upper half 8-bit units. Using the multiplexers controlled by the PINT\_ASSIGN register, the lower half units of eight pins can be forwarded to either byte 0 or byte 2 of either associated PINT block, and the upper half units can be forwarded to either byte 1 or byte 3 of the PINT block, without further restrictions.

## Pint Pinstate Register

When a half port is assigned to a byte in any PINT block, the state of the eight pins (regardless of GPIO or function, input or output) can be seen in the `PINT_PINSTATE` register. While neither input nor output drivers of the pin are enabled, reads of the pin state in `PINT_PINSTATE` return zero. The `PINT_PINSTATE` register reports the inverted state of the pin if the signal inverter is activated by the `PINT_INV_SET` register. The inverter can be enabled on a individual bit by bit basis. Every bit in the `PINT_INV_SET` and `PINT_INV_CLR` register pair represents a pin signal.

The pin interrupt pin state registers enable the service routine to read the current state of the pin without reading from GPIO space. If there was an edge-sensitive interrupt, the service routine can check whether the state of the pin is still high or turned low.

PINT\_PINSTATE: Pint Pinstate Register - R/WE

## Pint Latch Register

The `PINT_LATCH` register indicates interrupt latch status for pin interrupts. When set, an interrupt request is latched. When cleared, there is no interrupt request latched.

Both the `PINT_REQ` and `PINT_LATCH` registers indicate whether an interrupt request is latched on the respective pin. The `PINT_LATCH` register is a latch that operates regardless of the interrupt masks. Bits of the `PINT_REQ` register depend on the mask register. The `PINT_REQ` register is a logical AND of the `PINT_LATCH` register and the interrupt mask.

Having two separate registers here enables the user to interrogate certain pins in polling mode while others work in interrupt mode. The `PINT_LATCH` registers can be used for edge detection or pin activity detection.

Both registers have W1C behavior. Writing a 1 to either clears respective bits in both registers. For interrupt operation, the user may prefer to W1C the `PINT_REQ` register (address still loaded in Px pointer). In polling mode it might be cleaner to W1C the `PINT_LATCH` register.

Regardless whether in edge-sensitive mode or level-sensitive mode, `PINT_LATCH` bits are never cleared by hardware except at system reset. Even in level-sensitive mode, the `PINT_LATCH` register functions as latch.

PINT\_LATCH: Pint Latch Register - R/W

Reset = 0x0000 0000

# 15 General-Purpose Timer (TIMER)

The general-purpose timer (TIMER) module serves as a collection of system timers that support various system-level functions. These functions include synchronized PWM waveform output capability, external signal capture, external event count, and general time base functionality. Additionally, a variety of interrupts can be generated upon completion of timer events. Moreover, GP timers can act both as trigger masters and trigger slaves.

## TIMER Features

Each timer can be individually configured in any of these modes:

- Pin interrupt capture mode
- Windowed Watchdog mode
- Pulse-width Count and Capture (WDTH\_CAP) mode
- External Event (EXT\_CLK) mode
- Pulse-width Modulation (PWM\_OUT) mode

Other features include:

- Synchronous operation
- Consistent management of period and pulse width values
- Autobaud detection for UART module (where available)
- Graceful bit pattern termination when stopping
- Support for center-aligned PWM patterns
- Error detection on implausible pattern values
- All read and write accesses to 32-bit registers are atomic
- Every timer has its dedicated interrupt request output
- Unused timers can function as edge-sensitive pin interrupts

**NOTE:**

Each timer has a `EMURUN` bit in its `TIMER_TMRn_CFG` register which controls whether to run or stop the timer during emulation. The emulation event is controlled by the SDU (System Debug Unit). Please refer to the SDU chapter for more details on generation of an emulation event.

## TIMER Register List

**Table 15-1:** TIMER Module Registers

| Name               | Description                       |
|--------------------|-----------------------------------|
| TIMER_REVID        | Revision ID Register              |
| TIMER_RUN          | Run Register                      |
| TIMER_RUN_SET      | Run Set Register                  |
| TIMER_RUN_CLR      | Run Clear Register                |
| TIMER_STOP_CFG     | Stop Configuration Register       |
| TIMER_STOP_CFG_SET | Stop Configuration Set Register   |
| TIMER_STOP_CFG_CLR | Stop Configuration Clear Register |
| TIMER_DATA_IMSK    | Data Interrupt Mask Register      |
| TIMER_STAT_IMSK    | Status Interrupt Mask Register    |
| TIMER_TRG_MSK      | Trigger Master Mask Register      |
| TIMER_TRG_IE       | Trigger Slave Enable Register     |
| TIMER_DATA_ILAT    | Data Interrupt Latch Register     |
| TIMER_STAT_ILAT    | Status Interrupt Latch Register   |
| TIMER_ERR_TYPE     | Error Type Status Register        |
| TIMER_BCAST_PER    | Broadcast Period Register         |
| TIMER_BCAST_WID    | Broadcast Width Register          |
| TIMER_BCAST_DLY    | Broadcast Delay Register          |

**Table 15-1:** TIMER Module Registers (Continued)

| Name           | Description                    |
|----------------|--------------------------------|
| TIMER_TMRn_CFG | Timer n Configuration Register |
| TIMER_TMRn_CNT | Timer n Counter Register       |
| TIMER_TMRn_PER | Timer n Period Register        |
| TIMER_TMRn_WID | Timer n Width Register         |
| TIMER_TMRn_DLY | Timer n Delay Register         |

## ADSP-BF60x TIMER Interrupt List

**Table 15-2:** ADSP-BF60x TIMER Interrupt List

| Description    | ID | DMA Channel | Sensitivity |
|----------------|----|-------------|-------------|
| TIMER0 Timer 0 | 12 |             | LEVEL       |
| TIMER0 Timer 1 | 13 |             | LEVEL       |
| TIMER0 Timer 2 | 14 |             | LEVEL       |
| TIMER0 Timer 3 | 15 |             | LEVEL       |
| TIMER0 Timer 4 | 16 |             | LEVEL       |
| TIMER0 Timer 5 | 17 |             | LEVEL       |
| TIMER0 Timer 6 | 18 |             | LEVEL       |
| TIMER0 Timer 7 | 19 |             | LEVEL       |
| TIMER0 Status  | 20 |             | LEVEL       |

## ADSP-BF60x TIMER Trigger List

**Table 15-3:** Masters ADSP-BF60x TIMER Trigger List

| Description    | ID | Sensitivity |
|----------------|----|-------------|
| TIMER0 Timer 0 | 2  | PULSE/EDGE  |

**Table 15-3:** Masters ADSP-BF60x TIMER Trigger List (Continued)

| Description    | ID | Sensitivity |
|----------------|----|-------------|
| TIMER0 Timer 1 | 3  | PULSE/EDGE  |
| TIMER0 Timer 2 | 4  | PULSE/EDGE  |
| TIMER0 Timer 3 | 5  | PULSE/EDGE  |
| TIMER0 Timer 4 | 6  | PULSE/EDGE  |
| TIMER0 Timer 5 | 7  | PULSE/EDGE  |
| TIMER0 Timer 6 | 8  | PULSE/EDGE  |
| TIMER0 Timer 7 | 9  | PULSE/EDGE  |
|                |    |             |

| Description    | ID | Sensitivity |
|----------------|----|-------------|
| TIMER0 Timer 0 | 2  |             |
| TIMER0 Timer 1 | 3  |             |
| TIMER0 Timer 2 | 4  |             |
| TIMER0 Timer 3 | 5  |             |
| TIMER0 Timer 4 | 6  |             |
| TIMER0 Timer 5 | 7  |             |
| TIMER0 Timer 6 | 8  |             |
| TIMER0 Timer 7 | 9  |             |
|                |    |             |

## TIMER Internal Interface

Timer registers are always accessed by the processor core through the MMR access bus. Hardware ensures that all read and write operations from and to 32-bit timer registers are atomic. Every timer has its dedicated data interrupt request. There is also one common timer status/error interrupt request output that connects to the System Event Controller. Whenever a data interrupt is generated, a data Trigger Master pulse is also driven out, if enabled. Each timer has an individual trigger input line, and each timer can be either started or stopped as a Trigger Slave.

In total, the TIMER module can have up to  $(N + 1)$  interrupt output lines and  $N$  data trigger lines.

## TIMER External Interface

Each GP TIMER module can support up to 16 individual timers. However, most processors have less than this number. The exact number of timers available on a given processor is available in that processor's data sheet.

Every timer has one main input/output signal ( $TMR_x$ ) and, usually, one auxiliary input pin, used as an alternate capture input ( $TM\_ACIx$ ). Each TMR can either run with a time base of  $SCLK$  or can reference an external clock on one of two  $TMR\_ALT\_CLKx$  pins. The  $TMR\_ALT\_CLK0$  signal maps to individual alternate clock ( $TM\_ACLKx$ ) pins for one or more timers. For instance, a  $TM\_ACLK3$  pin would provide an alternate site to supply an external signal that would serve as TMR3's reference clock. Likewise, the  $TMR\_ALT\_CLK1$  signal from each timer unit is connected together internally to provide a single global timer clock pin ( $TM0\_CLK$ ) for the GP timer module, for use as an additional time base.

When clocked internally from  $SCLK$ , the maximum period for the timer count is  $((2^{32})-1) / SCLK$  (in MHz)). For  $SCLK=133$  MHz, this would equate to 32.2 seconds. The  $TM\_ACLK$  and  $TM\_ACI$  capture input pins are sampled every  $SCLK$  cycle. The duration of every low or high state must be slightly more than one  $SCLK$  cycle. Therefore the maximum allowed frequency of timer input signals is slightly less than  $SCLK/2$ . For exact timing requirements, please refer to the processor's data sheet).

## TIMER General Operation

The core of every timer is a 32-bit counter that can be interrogated through the read-only  $TIMER\_TMR\_CNT$  register. Once a timer has been enabled, its  $TIMER\_TMR\_CNT$  register is loaded with a starting value.

A timer can operate in one of several different modes, configured through the  $TIMER\_TMR\_CFG$  register for that timer. These modes are known as PWMOUT, EXTCLK, WIDCAP, WATCHDOG, PININT and IDLE, and are summarized in the following table.

**Table 15-5:** Timer Mode Descriptions

| Timer Mode | Description                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PWMOUT     | Generates single or continuous PWM waveforms with programmable pulse width, period and delay                                                                                             |
| EXTCLK     | Counts “clock ticks” from the system clock (SCLK) or an externally applied waveform                                                                                                      |
| WIDCAP     | Captures pulse width or period of an externally applied waveform                                                                                                                         |
| WATCHDOG   | Monitors pulse width or period of an external signal and compares against a window of acceptable values, optionally generating an interrupt if it falls inside or outside of that window |
| PININT     | Can generate an interrupt on an active edge applied to a timer pin.                                                                                                                      |
| IDLE       | Idle; no activity                                                                                                                                                                        |

## Timer Period, Width and Delay Register Interaction

When the timer is started, writes to the buffer registers are immediately copied through to the period, pulsewidth, and delay registers. Therefore, these values are ready for use in the first timer period. When a timer is already running, software can write new values to the `TIMER_TMR_PER`, `TIMER_TMR_WID` and `TIMER_TMR_DLY` registers. The written values are buffered and do not update into the registers until the end of the current period (when the value in `TIMER_TMR_CNT` equals the value in `TIMER_TMR_PER`).

If new values are not written to these registers, the value from the previous period is re-used. Writes to these registers are atomic; it is not possible for the high word to be written without the low word also being written. All three registers are double buffered. Values written to the period, pulsewidth, and delay registers are always stored in the buffer registers. Reads from the same register always return the current, active value of period, pulse width or delay value. Written values are not read back until they become active.

The usage of the `TIMER_TMR_PER`, `TIMER_TMR_WID` and `TIMER_TMR_DLY` registers varies, depending on the mode of the timer and is specified by `TIMER_TMR_CFG.TMODE` bits. See the table below for more information.

**Table 15-6:** Usage of the Period, Width and Delay Registers in Different Timer Modes

| Timer Mode | Period       | Width        | DELAY        |
|------------|--------------|--------------|--------------|
| IDLE       | Not writable | Not writable | Not writable |

**Table 15-6:** Usage of the Period, Width and Delay Registers in Different Timer Modes (Continued)

| Timer Mode | Period                                                                                                                                                                                  | Width                                                                                                                                                                                   | DELAY                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WATCHDOG   | Can be updated on-the-fly. New value takes effect either upon timer start or when an asserting edge on the input signal is sensed.                                                      | Read-only. Retains value of last measured width or period of the input signal.                                                                                                          | Can be updated on-the-fly. New value takes effect either upon timer start or when an asserting edge on the input signal is sensed.                                                      |
| WIDCAP     | Read-only. Period value captured at the appropriate time and updated from its buffer register simultaneously with the Width register.                                                   | Read-only. **NOTE:** It is important to note that, if in a particular timer mode any of these three registers is not used, then software is not allowed to write into the unused one(s). For example, in WIDCAP mode, delay registers are not used. Therefore, software is not allowed to write any value to `TIMER_TMR_DLY`. The software must program `TIMER_TMR_CFG.TMODE` bits before programming these 3 registers, in order to prevent undesired operation.

Also, if software is changing `TIMER_TMR_CFG.TMODE` bits such that these registers change configuration from status register to writable register (for example for PWMOUT mode), hardware does not clear these registers. These values are automatically overwritten by new values specified by software.

In PWM\_OUT mode with very small periods, there may not be enough time between updates from the buffer registers to write these registers; the next period may use one old value and one new value. In order to prevent  $(\text{width} + \text{pulse delay}) > \text{period}$  errors, write the width and delay registers before the period register when decreasing the values, and write the period register before the width and delay registers when increasing the value.

## TIMER Programming Concepts

Using the features, operating modes, and event control for the GP Timer to their greatest potential requires an understanding of some GP Timer related concepts.

### Setting Up Constantly Changing Timer Conditions

This task shows how to use different period, pulse width, and/or delay settings for each of the first three timer periods after the timer is started.

1. Program the first set of period, width and delay register values.
2. Enable the timer.
3. Immediately program the second set of register values, as needed.
4. Wait for the first timer interrupt.
5. Program the third set of register values.

*RESULT:*

Each new setting is then programmed when the preceding timer interrupt is received.

### Configuring, Enabling and Disabling One or More Timers

1. Configure the relevant timer(s) for the operating mode and other properties through the `TIMER_TMR_CFG` register.
2. Write a 1 to the representative `TIMER_RUN` bit(s) or, alternately, use the `TIMER_RUN_SET` register to avoid disturbing the settings of other timers not being presently configured.

*STEP RESULT:* The timer(s) should now be enabled and operating.

3. To stop one or more timers, first program the `TIMER_STOP_CFG` register to determine whether to stop immediately or gracefully upon receiving a stop command.

*ADDITIONAL INFORMATION:* Note that PWMOUT modes are the only modes where a timer can be configured for graceful termination.

4. Write a 0 to the representative `TIMER_RUN` bit(s) to stop the timer(s) according to their `TIMER_STOP_CFG` settings. Alternately, write a 1 to the appropriate `TIMER_RUN_CLR` bits to avoid disturbing the settings of other timers not being presently stopped.

*STEP RESULT:* The timer(s) should now be stopped.

## Configuring Timer Data and Status Interrupts

1. Program the proper value in the `TIMER_TMR_IRQMODE` field, according to the desired interrupt properties.
2. Unmask the interrupt source at the system event controller.
3. To poll the timer's `TIMER_DATA_ILAT` bit without generating an interrupt, set the `IRQMODE` field but leave the interrupt masked at the system level.
4. If enabled by the `TIMER_STAT_IMSK` register, interrupt requests are also generated by overflow or error conditions (wrong programming values), as reported by the `TMR_STAT_ILAT` bits, provided that the timer status interrupt source is unmasked at the system event controller.
5. To poll the timer's `TIMER_STAT_ILAT` bit without generating an interrupt, the corresponding bit must be unmasked in the `TIMER_STAT_IMASK` register but leave the interrupt masked at the system level.

## Using the Timer Broadcast Feature

The broadcast feature provides a means to update period, width and/or delay registers simultaneously across more than one timer.

1. Enable the appropriate broadcast bits (`BPEREN`, `BWIDEN`, `BDLYEN`) in the `TIMER_TMR_CFG` registers for the timers involved in the broadcast. The broadcast bits use depend on which `TIMER_BCAST` registers are involved.
2. Program the `TIMER_BCAST_PER` register (for instance), assuming you want to broadcast the period setting across the multiple timers enabled above.

*STEP RESULT:* This causes only those timers enabled above to load their `TIMER_TMR_PER` registers with the value specified in the `TIMER_BCAST_PER` register.

3. Repeat Step 2 as needed for `TIMER_BCAST_WID` and `TIMER_BCAST_DLY` settings.

## Timer Single-Pulse PWMOUT Mode

In single-pulse PWMOUT mode, the timer generates a single pulse on the TMR pin. This mode is frequently used to implement a precise delay, often in conjunction with generation of an output trigger. The assertion of a pulse is controlled by the value in `TIMER_TMR_DLY`, and pulse width is defined by the `TIMER_TMR_WID` value. `TIMER_TMR_PER` is not used and cannot be written in this mode. After completion of the pulse the timer is stopped automatically, optionally generating an interrupt, if configured to do so. Pulse polarity is controlled through the `TIMER_TMR_CFG.PULSEHI` bit.

If configured as such, the timer can generate a data interrupt upon satisfying various conditions specified by the `TIMER_TMR_CFG.IRQMODE` bits.

It is not necessary to clear the relevant `TIMER_RUN` bit in order to stop the timer cleanly. At the end of the pulse, the timer stops automatically and the corresponding `TIMER_RUN` is cleared. To generate multiple discrete pulses (as opposed to a continuous PWM waveform), write a 1 to the appropriate `TIMER_RUN` bit, wait for the timer to stop, and then write another 1 to the same `TIMER_RUN` bit.

## Timer Continuous PWMOUT Mode

In continuous PWMOUT mode, the timer generates repetitive pulses with well-defined period, duty cycle and pulse position. The `TIMER_TMR_DLY`, `TIMER_TMR_PER` and `TIMER_TMR_WID` registers are programmed with the values of the required PWM pulse. After the timer is started, the counter counts towards the value programmed in `TIMER_TMR_PER`. Initially, the TMR pin remains in a de-asserted state. It toggles to an asserted state when `TIMER_TMR_CNT=TIMER_TMR_DLY`. The assertion sense of the TMR pin can be controlled with the `TIMER_TMR_CFG.PULSEHI` bit. The TMR pin holds this value for the number of clock cycles specified in `TIMER_TMR_WID`, after which it de-asserts and holds this value until the completion of the programmed period. The same waveform is generated repeatedly until the timer is disabled.

If configured as such, the timer can generate a data interrupt upon satisfying any of various conditions specified by the `TIMER_TMR_CFG.IRQMODE` bits.

It is important to guarantee that the programmed Period  $\geq$  (Width+Delay). Similarly, delay must be less than period. Violating either of these criteria will result in an unpredictable waveform on the TMR pin until the situation is rectified by writing proper values to these registers.

The maximum frequency possible to generate on the TMR pin is achieved by setting `TIMER_TMR_PER` to 2 and `TIMER_TMR_WID` to 1. This makes the TMR pin toggle each `SCLK` clock cycle (assuming the timer is configured to clock internally), producing a duty cycle of 50%. For instance, if `SCLK` is running at 166 MHz, the maximum frequency generated at the TMR pin is  $((2^{32} - 1) / 166 \text{ MHz})$ , or 25.87 seconds.

When a timer's `TIMER_STOP_CFG` bit is 0, the timer treats a stop operation as a stop is pending condition. When terminated with this setting, the timer automatically completes the current waveform and then stops cleanly, remaining in a deasserted state. This prevents truncation of the current pulse and unwanted PWM patterns at the TMR pin. The processor can determine when the timer stops running by polling the corresponding `TIMER_RUN` bit until it reads as read 0 or by waiting for the last interrupt (if enabled).

**Figure 15-1:** Signal Generation in Continuous PWMOUT Mode

Note that the `TIMER_TMR_CFG` register cannot be reconfigured until after the timer stops and `TIMER_RUN` reads 0.

If required, the software can force a timer to stop immediately in PWM\_OUT mode by writing a 1 into `TIMER_STOP_CFG` followed by writing a 1 to `TIMER_RUN_CLR` (or by writing a 0 to the appropriate `TIMER_RUN` bit). This stops the timer whether the pending stop was waiting for the end of the current period or the end of the current pulse width. This feature may be used to regain immediate control of a timer during an error recovery sequence.

Use this feature carefully, because it may corrupt the PWM pattern generated at the TMR pin, though after such a stop the pin deasserts automatically. Each timer samples its `TIMER_RUN` bit at the end of each period. It stops cleanly at the end of the first period after `TIMER_RUN` is low. This implies that a timer that is disabled and then re-started, all before the end of the current period, will continue to run as if nothing happened. Typically, software should disable a PWMOUT timer and then wait for it to stop itself.

## TIMER Width Capture (WIDCAP) Mode

The WIDCAP mode, often simply called capture mode, is used to measure pulse widths on the TMR or TMR\_AUX\_IN inputs. The polarity (active high/low) of the input signal can be selected with the `TIMER_TMR_CFG.PULSEHI` bit. The figure below shows the control signal flow for WIDCAP\_CAP mode.

**Figure 15-2:** Timer Signal Flow in Width Capture Mode

In this mode, the `TIMER_TMR_CFG.TINSEL` bit selects between the TMR or TMR\_AUX\_IN input. The internally clocked timer is used to determine the period and pulse width of the externally applied rectangular waveforms.

When a timer is enabled in this mode, the timer resets the count in its `TIMER_TMR_CNT` register to 0x0000 0001 and does not start counting until it detects a leading edge on the selected input pin.

When the timer detects the first leading edge, it starts incrementing. When it detects a trailing edge of a waveform, it captures the current 32-bit value of its `TMR_CNT` register into its width buffer register. At the next leading edge, the timer transfers the current 32-bit value of its `TMR_CNT` register into its period buffer register. The `TMR_CNT` register is reset to 0x0000 0001 again, and the timer continues counting and capturing until it is disabled.

In this mode, software can measure both the pulse width and the pulse period of a waveform. The `TMR_DLY` register is not used in this mode. The `TIMER_TMR_CFG.PULSEHI` bit controls the definition of leading edge and trailing edge of the TMR/TMR\_AUX\_IN pin.

In WIDCAP mode, the following events always occur at the same time as one unit:

1. The `TIMER_TMR_PER` register is updated from the period buffer register.
2. The `TIMER_TMR_WIDTH` register is updated from the width buffer register.
3. The `TIMER_DATA_ILAT` bit gets set (if enabled).

4. A timer data trigger pulse is generated (if enabled).

The `TIMER_TMR_CFG.TMODE[0]` bit controls the point in time at which this set of events is executed. Taken together, these four events are called a measurement report. The `TMR_STAT_ILAT` register does not get set at a measurement report. A measurement report occurs, at most, once per input signal period. The current `TMR_CNT` value is always copied to the width buffer and period buffer registers at the trailing and leading edges of the input signal, respectively, but these values are not visible to software. A measurement report event samples the captured values into visible registers and sets the timer interrupt to signal that `TMR_PER` and `TMR_WID` are ready to be read.

When `TMODE=b#1011`, the measurement report occurs just after the width buffer register captures its value (at a falling edge). Subsequently, the `TMR_WID` register reports the pulse width measured in the pulse that has just ended, but the `TMR_PER` register reports the pulse period measured at the end of the previous period. This is because, if only the first trailing edge occurred, then the first period value has not yet been measured at the first measurement report, so the period value is not valid. A read of the `TMR_PER` value in this case returns 0. See the following figure for more information.

NOTE: FOR SIMPLICITY, THE SYNCHRONIZATION DELAY BETWEEN TMRx EDGES AND BUFFER REGISTER UPDATES IS NOT SHOWN.

**Figure 15-3:** Example of Width Capture Deasserted Mode (`TMODE=b#1011`)

When  $TMODE=b\#1010$ , the measurement report occurs just after the period buffer register captures its value (at a leading edge). Subsequently, the  $TMR\_PER$  and  $TMR\_WID$  registers report the pulse period and pulse width is measured in the period that has just ended. Refer to the following figure for more information.

**Figure 15-4:** Example of Width Capture Asserted Mode ( $TMODE=b\#1010$ )

To measure the pulse width of a waveform that has only one leading edge and one trailing edge, set  $TMODE = b\#1011$ . If  $TMODE = b\#1010$  for this case, no period value is captured in the period buffer register. Instead, an error report interrupt is generated (if enabled) when the  $TMR\_CNT$  range is exceeded and the counter wraps around. In this case, both  $TMR\_WID$  and  $TMR\_PER$  read 0 (because no measurement report occurred to copy the value captured in the width buffer register to  $TMR\_WID$ ).

If using the  $TMODE = b\#1010$  mode to measure the width of a single pulse, it is recommended to disable the timer after taking the interrupt that ends the measurement interval. If desired, the timer can then be restarted as appropriate in preparation for another measurement. This procedure prevents the timer from free-running after the width measurement and logging errors generated by the timer count overflowing.

## GP Timer Width Capture Mode Overflow

A timer status interrupt (if enabled) is generated if the `TMR_CNT` register wraps around from `0xFFFF FFFF` to 0 in the absence of a leading edge. At that point, the timer's `TIMER_STAT_ILAT` bit gets set and the `TIMER_ERR_TYP` bits change appropriately, indicating a count overflow due to a period greater than the counter's range. This is called an error report. A data interrupt in WIDCAP mode indicates a new measurement is ready to be read (a measurement report). Similarly, an interrupt on the timer status interrupt line (shared interrupt for all timers) indicates an overflow if generated in WIDCAP mode.

The `TMR_PER` and `TMR_WID` registers are never updated at the time an overflow is signaled. If the timer overflowed and `TMODE=b#1010`, neither the `TMR_PER` nor the `TMR_WID` register were updated. If the timer overflowed and `TMODE=b#1011`, the `TMR_PER` and `TMR_WID` registers were updated only if a trailing edge was detected at a previous measurement report.

Software can count the number of error reports between measurement report interrupts to measure input signal periods longer than `0xFFFF FFFF`. Each error report interrupt adds a full  $2^{32}$  SCLK counts to the total for the period, but the width is ambiguous. Make sure that, if only the status interrupt is monitored by software in this case, then status interrupts from all other timers are masked.

For example, in the following figure, the period is `0x1 0000 0004`, but the pulse width could be either `0x0 0000 0002` or `0x1 0000 0002`.

NOTE: FOR SIMPLICITY, THE SYNCHRONIZATION DELAY BETWEEN TMRx EDGES AND BUFFER REGISTER UPDATES IS NOT SHOWN.

**Figure 15-5:** Example Timing for Width Capture Followed by Period Overflow (TMR\_CFG.TMODE=b#1010)

The waveform applied to the TMR (or TMR\_AUX\_IN) pin is not required to have a 50% duty cycle, but the minimum input low time is little more than one SCLK period and the minimum input high time is little more than one SCLK period (refer to the product data sheet for details). This implies the maximum TMR input frequency is somewhat less than  $SCLK/2$ , with a 50% duty cycle. Under these conditions, the WIDCAP mode timer would measure Period = 2 and Pulse Width = 1.

**Figure 15-6:** Example Timing for Width Capture Followed by Period Overflow (TMR\_CFG.TMODE=b#1011)

## TIMER Windowed Watchdog (WATCHDOG) Modes

In windowed watchdog (WATCHDOG) modes, a timer can take inputs from either the TMR pin or the TMR\_AUX\_IN pin. With this mode, the timer can monitor pulse width (width watchdog mode) or pulse period (period watchdog mode) on the input line. It also compares the measured value against a minimum required value and maximum allowed value and generates an interrupt appropriately. Polarity selection of the input signal is performed by the `TIMER_TMR_CFG.PULSEHI` bit.

The waveform applied to the input pin in watchdog mode is not required to have a 50% duty cycle, but the minimum input pulse low time is slightly more than one SCLK period, and the minimum input pulse high time is slightly more than one SCLK period (refer to the product data sheet for details). This implies the maximum input frequency is somewhat less than  $SCLK/2$  in this mode.

## Timer Windowed Watchdog Width Mode

In this mode, the timer counter monitors the pulse width of an input signal on either the TMR pin or TMR\_ALT\_CLK pin. Software needs to program the minimum pulse width (Pmin) in the `TIMER_TMR_DLY` register and the maximum pulse width (Pmax) in the `TIMER_TMR_PER` register. Both values are programmed in terms of number of clock cycles (SCLK or TMR\_ALT\_CLKx). The timer can generate an interrupt if the deasserting pulse edge occurs inside the window ( $P_{min} < \text{Pulse Width} \leq P_{max}$ ) or outside the window ( $\text{Pulse Width} \leq P_{min}$  or  $\text{Pulse Width} > P_{max}$ ).

After enabling the timer in this mode, it always starts counting at the asserting edge of the input signal. This means any pulse that is already active when the timer is enabled is ignored.

With `TIMER_TMR_CFG.IRQMODE=b#11`, the timer generates an interrupt (if enabled) if the timed pulse width exceeds Pmax, or if the pulse width is less than Pmin. After attaining Pmax, the pulse still remains at an active level, and the counter keeps on counting until it sees a deasserting edge. When the input pulse is not active, the counter holds its current value until it again sees an asserting edge, or it restarts. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting `TIMER_TMR_CFG.IRQMODE=b#10`.

In this mode, a trailing edge on the input pin triggers capturing of pulse width into the `TIMER_TMR_WID` register. During the inactive portion of the input signal, the internal counter does not increment. Refer to the figure below for signal flow in this mode.

**Figure 15-7:** Watchdog Width Mode Timing

If it is required to check only the upper limit on pulse width (Pmax but not Pmin) then Pmin must be programmed as 0 or 1. In such a case, it is better to use `IRQ_MODE = b#11`. With `IRQ_MODE = b#10`, a pulse width of 1 clock cycle will result in an interrupt. For details see the table below.

**Table 15-7:** Windowed Watchdog Width Mode Interpretation

| Timer Delay                | Timer Period      | Incoming Pulse Width        | IRQMODE= b#10                                 | IRQMODE= b#11                                                  | Error Interrupt?   |
|----------------------------|-------------------|-----------------------------|-----------------------------------------------|----------------------------------------------------------------|--------------------|
| 0 or 1                     | Anything $\geq 1$ | PW = 1                      | Interrupt at deasserting edge of input signal | No Interrupt                                                   | No Error Interrupt |
|                            |                   | PW $\leq$ TMR_PER           | Interrupt at deasserting edge of input signal | No Interrupt                                                   | No Error Interrupt |
|                            |                   | PW > TMR_PER                | No Interrupt                                  | Interrupt when Pulse with exceeds Pmax (Period Register) Value | No Error Interrupt |
| > 1 but $\leq$ (Period -1) | Anything > 1      | PW $\leq$ TMR_DLY           | No Interrupt                                  | Interrupt at De-asserting edge of input Signal                 | No Error Interrupt |
|                            |                   | TMR_DLY < PW $\leq$ TMR_PER | Interrupt at deasserting edge of input signal | No Interrupt                                                   | No Error Interrupt |
|                            |                   | PW > TMR_PER                | No Interrupt                                  | Interrupt when Pulse with exceeds Pmax (Period Register) Value | No Error Interrupt |
| $\geq$ Period              | -                 | PW $\leq$ TMR_PER           | Undefined                                     | Undefined                                                      | No Error Interrupt |
|                            | -                 | PW > TMR_PER                | Undefined                                     | Undefined                                                      | b#11 Error Type    |
| -                          | 0                 | -                           | Undefined                                     | Undefined                                                      | b#10 Error Type    |

Timer Windowed Watchdog Period Mode

In this mode, the timer monitors the number of clock cycles between two consecutive rising/falling edges of an input signal on either the TMR pin or TMR\_AUX\_IN pin. Software needs to program the required minimum number of clock cycles (Tmin) in the TIMER\_TMR\_DLY register and the required maximum allowed number of clock cycles (Tmax) in the TIMER\_TMR\_PER register. Both values are programmed in terms of number of clock cycles (SCLK or TMR\_ALT\_CLKx). The timer can generate an interrupt if two consecutive occurrences of an active edge are within a specified window ( $T_{min} < \text{Pulse Period} \leq T_{max}$ ) or outside ( $\text{Pulse Width} \leq T_{min}$  or  $T_{max} < \text{Pulse Width}$ ) a specified window.

With `TIMER_TMR_CFG.IRQMODE=b#11`, if the pulse period ever exceeds Tmax or if it is less than or equal to Tmin, the timer generates an interrupt if unmasked. After attaining the Tmax value, the counter keeps on counting until it sees an active edge on the input line. An interrupt can also be generated for when the pulse occurs within the specified window condition, by setting `TIMER_TMR_CFG.IRQMODE=b#10`. Refer to the figure below for timer functionality in period watchdog mode.

Figure 15-8: Watchdog Period Mode Timing

If it is required to check only the upper limit on period (Tmax value but not Tmin value) then Tmin can be programmed as 0 or 1 in this mode. For details refer to the table below.

**Table 15-8:** Windowed Watchdog Period Mode Interpretation

| Timer Delay                   | Timer Period      | Incoming Pulse Width                    | IRQMODE=b#10                                  | IRQMODE =b#11                                                    | Error Interrupt?   |
|-------------------------------|-------------------|-----------------------------------------|-----------------------------------------------|------------------------------------------------------------------|--------------------|
| 0 or 1                        | Anything $\geq 2$ | Pulse Period $\leq$ TMR_PER             | Interrupt at deasserting edge of input signal | No Interrupt                                                     | No Error Interrupt |
|                               |                   | Pulse Period $>$ TMR_PER                | No Interrupt                                  | Interrupt when pulse period crosses Pmax (Period Register) value | No Error Interrupt |
| $\geq 1$ but $\leq$ Period -1 | Anything $\geq 2$ | Pulse Period $\leq$ TMR_DLY             | No Interrupt                                  | Interrupt at deasserting edge of input signal                    | No Error Interrupt |
|                               |                   | TMR_DLY $<$ Pulse Period $\leq$ TMR_PER | Interrupt at deasserting edge of input signal | No Interrupt                                                     | No Error Interrupt |
|                               |                   | Pulse Period $>$ TMR_PER                | No Interrupt                                  | Interrupt when pulse width exceeds Pmax (Period Register) value  | No Error Interrupt |
| $\geq$ Period                 | -                 | Pulse Period $<$ TMR_PER                | Undefined                                     | Undefined                                                        | No Error Interrupt |
|                               |                   | Pulse Period $\geq$ TMR_PER             | Undefined                                     | Undefined                                                        | b#11 Error Type    |

## TIMER Pin Interrupt (PININT) Mode

In PININT mode, any active edges on either the TMR pin or the TMR\_AUX\_IN pin (whichever is selected by `TIMER_TMR_CFG.TINSEL`) can cause an edge-based interrupt if enabled. The event on the input pin can

set the `TIMER_DATA_ILAT` bit and issue a system interrupt request. Active edge polarity can be changed by programming the `TIMER_TMR_CFG.PULSEHI` bit.

Since the interrupt is generated in the `SCLK` clock domain, the width of the input signal must be more than one `SCLK` period. Along with generating the interrupt, the timer will also generate a trigger pulse if it is enabled in the `TIMER_TRG_MSK` register. Due to configuration of polarity, glitches at the input may cause an undesired interrupt to be generated. To avoid this, software must ensure that interrupts are unmasked only after configuring desired polarity.

## TIMER External Clock (EXTCLK) Mode

Use the `EXTCLK` mode, sometimes referred to as the counter mode, to count external events, that is, signal edges on either the `TMR` or `TMR_AUX_IN` input pin. The timer works as a counter clocked by an external source (the signal at the pin), which can be asynchronous to `SCLK`. The current count in `TIMER_TMR_CNT` represents the number of leading edge events detected. The `TIMER_TMR_PER` register is programmed with the value of the maximum timer external count desired before stopping and/or issuing an interrupt or trigger.

The `TIMER_TMR_CFG.PULSEHI` bit determines the polarity of the leading edge on the input pin. The `TIMER_TMR_CFG.TINSEL` bit selects whether event is counted on `TMR` pin or on the `TMR_AUX_IN` pin. The `TIMER_STAT_ILAT` and `TIMER_ERR_TYP` bits are set if `TIMER_TMR_CNT` wraps around from `0xFFFF FFFF` to 0 or if the period = 0 at startup or when `TIMER_TMR_CNT` rolls over (from count = period to count = 0x1). The `TIMER_TMR_WID` and `TIMER_TMR_DLY` registers are unused in this mode.

The figure below shows a flow diagram for `EXTCLK` mode.

**Figure 15-9:** EXTCLK Mode Control Flow

The waveform applied to the input pin is not required to have a 50% duty cycle, but the minimum input low time and input high time are both slightly more than one `SCLK` period, (refer to the product data sheet

for details). This implies the maximum input frequency is slightly less than  $SCLK/2$ . The period may be programmed to any value from 1 to  $(2^{32} - 1)$ , inclusive.

After the timer has started, it resets `TIMER_TMR_CNT` to 0x0 and then waits for the first leading edge on the input pin. This edge causes `TMR_CNT` to be incremented to the value 0x1, and every subsequent leading edge increments it by one. After `TMR_CNT` reaches the value programmed in `TIMER_TMR_PER`, the corresponding `TIMER_DATA_ILAT` bit is set, and an interrupt and trigger are both generated (if enabled). The next leading edge reloads the `TMR_CNT` again with 0x1, and the timer continues counting until it is disabled.

## Timer Illegal States

These definitions are used in the table below:

- **Startup.** The first clock period during which the timer counter is running after the timer is started by writing the `TIMER_RUN` register.
- **Rollover.** The time when the current count in `TMR_CNT` matches the value in `TMR_PER` and the counter is reloaded with the value 1.
- **Overflow.** The timer counter was incremented instead of doing a rollover when it was holding the maximum possible count value of 0xFFFF FFFF. The counter does not have a large enough range to express the next greater value and so erroneously loads a new value of 0x0000 0000.
- **Unchanged.** No new error.

When `ERR_TYPE` is designated unchanged, it displays the previously reported error code orb# 00 if there has been no error since this timer was enabled.

When `TIMER_STAT_ILAT` is unchanged, it reads 0 if there has been no error or overflow since this timer was enabled, or if software has performed a W1C to clear any previous error. If a previous error has not been acknowledged by software, `STAT_ILAT` reads 1. Software should read `STAT_ILAT` to check for an error. If a particular timer's bit is set there, software can then read `TIMER_ERR_TYPE` for more information. Once detected, software should W1C the appropriate `STAT_ILAT` bit to acknowledge the error.

The following tables can be read as: “In mode \_\_ at event \_\_, if `TMR_PER` is \_\_ and `TMR_WID` is \_\_ and `TMR_DLY` is \_\_, then `TIMER_ERR_TYPE` is \_\_ and `TIMER_STAT_ILAT` is \_\_.” Startup error conditions do not prevent the timer from starting. Similarly, overflow and rollover error conditions do not stop the timer. Illegal cases may cause unwanted behavior of the TMR pin.

**NOTE:** For PININT mode error functionality is not used.

## Continuous PWMOUT Mode

**Table 15-9:** Startup Event

| TMR_PER | TMR_DLY                                             | MR_WID                  | TMR_WID +<br>TMR_DLY | ERR_TYPE                                  | TIMER_STAT_ILAT (if<br>enabled)     |

## Single Pulse PWMOUT Mode

For Single Pulse PWMOUT mode, there are no rollover events.

**Table 15-12:** Startup Event

| TMR_PER | TMR_DLY              | TMR_WID | TMR_WID +<br>TMR_DLY | ERR_TYPE<br>TIMER_STAT<br>_ILAT (if<br>enabled) |           |
|---------|----------------------|---------|----------------------|-------------------------------------------------|-----------|
| NA      | Anything             | == 0    | Anything             | b#11[11]                                        | Set       |
| NA      | Anything including 0 | >=1     | $> 2^{32} - 1$       | Unchanged                                       | Unchanged |
| NA      | Anything including 0 | >=1     | $> 2^{32} - 1$       | b#11                                            | Set       |

**Table 15-13:** Overflow Event (On another error, such as DELAY + WIDTH  $\geq 2^{32} - 1$ )

| TMR_PER  | TMR_DLY  | TMR_WID  | TMR_WID +<br>TMR_DLY | ERR_TYPE | TIMER_STA_ILAT (if<br>enabled) |
|----------|----------|----------|----------------------|----------|--------------------------------|
| Anything | Anything | Anything | Anything             | b#01     | Set                            |

## WID CAP Mode

For WID CAP mode, the TMR\_PER and TMR\_WID registers are read-only and the TMR\_DLY register is not used. Therefore no startup or rollover errors are possible.

**Table 15-14:** Overflow Event

| TMR_PER  | TMR_DLY | TMR_WID  | TMR_WID +<br>TMR_DLY | ERR_TYPE | TIMER_STAT_ILAT (if<br>enabled) |

## TIMER Register Descriptions

General Purpose Timer Block (TIMER) contains the following registers.

**Table 15-21:** TIMER Module Registers

| Name               | Description                       |
|--------------------|-----------------------------------|
| TIMER_REVID        | Revision ID Register              |
| TIMER_RUN          | Run Register                      |
| TIMER_RUN_SET      | Run Set Register                  |
| TIMER_RUN_CLR      | Run Clear Register                |
| TIMER_STOP_CFG     | Stop Configuration Register       |
| TIMER_STOP_CFG_SET | Stop Configuration Set Register   |
| TIMER_STOP_CFG_CLR | Stop Configuration Clear Register |
| TIMER_DATA_IMSK    | Data Interrupt Mask Register      |
| TIMER_STAT_IMSK    | Status Interrupt Mask Register    |
| TIMER_TRG_MSK      | Trigger Master Mask Register      |
| TIMER_TRG_IE       | Trigger Slave Enable Register     |
| TIMER_DATA_ILAT    | Data Interrupt Latch Register     |
| TIMER_STAT_ILAT    | Status Interrupt Latch Register   |
| TIMER_ERR_TYPE     | Error Type Status Register        |
| TIMER_BCAST_PER    | Broadcast Period Register         |
| TIMER_BCAST_WID    | Broadcast Width Register          |
| TIMER_BCAST_DLY    | Broadcast Delay Register          |
| TIMER_TMRn_CFG     | Timer n Configuration Register    |
| TIMER_TMRn_CNT     | Timer n Counter Register          |
| TIMER_TMRn_PER     | Timer n Period Register           |

**Table 15-21:** TIMER Module Registers (Continued)

| Name           | Description            |
|----------------|------------------------|
| TIMER_TMRn_WID | Timer n Width Register |
| TIMER_TMRn_DLY | Timer n Delay Register |

## Revision ID Register

The `TIMER_REVID` holds the TIMER module revision information.

**TIMER\_REVID: Revision ID Register - R/NW**

Reset = 0x0030

**Figure 15-10:** TIMER\_REVID Register Diagram**Table 15-22:** TIMER\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration  |
|---------|----------|--------------------------|
| 7:4     | MAJOR    | Major Revision ID.       |
| 3:0     | REV      | Incremental Revision ID. |

## Run Register

The `TIMER_RUN` allows all timers to be enabled simultaneously, permitting them to run synchronously. For each timer, there is a single start/stop control bit. Writing a 1 to this bit starts the corresponding timer; writing a 0 stops the timer with mechanism specified in the timer stop configuration `TIMER_STOP_CFG` register.

The start/stop control bits can be set/reset individually or in any combination. While starting or stopping one particular timer directly with this register, software must perform a read-modify write, so the bits corresponding to other timers remain unchanged. To avoid this need, software can use the `TIMER_RUN_CLR` register.

Reading the `TIMER_RUN` register shows the start status for the corresponding timer. A 1 indicates that the timer is running.

If a timer is in run state (corresponding run bit is =1), a software write of 1 in this bit does not have any effect on the timer state. The write does not result in restarting the timer.

Note that the `TIMER_RUN` register is not used in PININT mode. PININT mode starts as soon as the `TIMER_TMRn_CFG.TMODE` bits are set to 111.

**TIMER\_RUN: Run Register - R/W**

Reset = 0x0000

**Figure 15-11:** TIMER\_RUN Register Diagram

**Table 15-23:** TIMER\_RUN Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                     |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Start/Stop Timer n.<br>For all <code>TIMER_RUN.TMRnn</code> bits, write =0 for stop, and write =1 for start. Read =1 when timer is running. |

Run Set Register

The `TIMER_RUN_SET` register is an alias register, providing a mechanism to set a specific start/stop bit in the `TIMER_RUN` register without affecting other bits in `TIMER_RUN`. To start a particular timer, software must write a 1 into the corresponding `TIMER_RUN_SET` bit. Writing a zero has no effect. For an example, to start timer 3 without affecting any other timer, write 0x0008 into `TIMER_RUN_SET`. Because `TIMER_RUN_SET` is a write-only register, the result of any write to this register must be checked by reading the `TIMER_RUN` register. A read of the `TIMER_RUN_SET` returns 0x0000.

**TIMER\_RUN\_SET: Run Set Register - R/WA**

Reset = 0x0000

**Figure 15-12:** TIMER\_RUN\_SET Register Diagram

**Table 15-24:** TIMER\_RUN\_SET Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                         |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | RUN Set Alias.<br>For all <code>TIMER_RUN_SET.TMRnn</code> bits, write =0 has no effect, and write =1 for start (setting the corresponding start/stop bit in the <code>TIMER_RUN</code> register). Using <code>TIMER_RUN_SET</code> to set start/stop bits permits starting specific timers without influencing the run status of other timers. |

## Run Clear Register

The `TIMER_RUN_CLR` register is an alias register, providing a mechanism to clear a specific start/stop bit in the `TIMER_RUN` register without affecting other bits in `TIMER_RUN`. To stop a particular timer, software must write a 1 into the corresponding `TIMER_RUN_CLR` bit. Writing a 0 has no effect. Because `TIMER_RUN_CLR` is a write-only register, the result of any write to this register must be checked by reading the `TIMER_RUN` register. A read of the `TIMER_RUN_CLR` returns 0x0000.

Note that the stopping mechanism of a timer may be abrupt or graceful (after completion of current waveform period) depending on the selection in the `TIMER_STOP_CFG` register.

**TIMER\_RUN\_CLR: Run Clear Register - R/WA**

Reset = 0x0000

**Figure 15-13:** TIMER\_RUN\_CLR Register Diagram

**Table 15-25:** TIMER\_RUN\_CLR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                            |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | RUN Clear Alias.<br>For all <code>TIMER_RUN_CLR.TMRnn</code> bits, write =0 has no effect, and write =1 for stop (clearing the corresponding in start/stop bit in the <code>TIMER_RUN</code> register). Using <code>TIMER_RUN_CLR</code> to clear start/stop bits permits stopping specific timers without influencing run status of other timers. |

## Stop Configuration Register

The `TIMER_STOP_CFG` selects the stop mode for each timer. Timers may be stopped abruptly (immediate halt - all modes) or gracefully in PWMOUT modes (single pulse and continuous). The halt is achieved through either a write =0 to the corresponding bit in `TIMER_RUN` or a write =1 to the corresponding bit in `TIMER_RUN_CLR`. A read of `TIMER_STOP_CFG` returns the last value written.

**TIMER\_STOP\_CFG: Stop Configuration Register - R/W**

Reset = 0x0000

**Figure 15-14:** TIMER\_STOP\_CFG Register Diagram

**Table 15-26:** TIMER\_STOP\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Stop Mode Select.<br>For all <code>TIMER_STOP_CFG.TMRnn</code> bits, write =0 for graceful termination (PWMOUT modes only), and write =1 for abrupt (immediate halt) on stop. |

## Stop Configuration Set Register

This is an alias register, providing a mechanism to set a specific bit in the `TIMER_STOP_CFG` register without affecting other bits in `TIMER_STOP_CFG`. To set a bit in `TIMER_STOP_CFG`, software must write a 1 to the corresponding bit of `TIMER_STOP_CFG_SET`. Writing a zero has no effect. Because `TIMER_STOP_CFG_SET` is a write-only register, the result of any write to this register must be checked by reading the `TIMER_STOP_CFG` register. A read of the `TIMER_STOP_CFG_SET` returns 0x0000.

**TIMER\_STOP\_CFG\_SET: Stop Configuration Set Register - R/WA**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | STOP_CFG Clear Alias.<br>For all TIMER_STOP_CFG_CLR.TMRnn bits, write =0 has no effect, and write =1 for graceful stop in PWMOUT modes (clearing the corresponding stop mode select bit in the TIMER_STOP_CFG register). Using TIMER_STOP_CFG_CLR to clear stop mode bits permits configuring specific timers without influencing the stop mode configuration of other timers. |

## Data Interrupt Mask Register

Each timer may generate a unique processor data interrupt request signal. The `TIMER_DATA_IMSK` contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the `TIMER_DATA_IMSK` register is `0xFFFF`, masking these interrupts after reset.

**TIMER\_DATA\_IMSK: Data Interrupt Mask Register - R/W**

Reset = 0x00ff

**Figure 15-17:** TIMER\_DATA\_IMSK Register Diagram

**Table 15-29:** TIMER\_DATA\_IMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                              |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Data Interrupt Mask.<br>For all <code>TIMER_DATA_IMSK.TMRnn</code> bits, write =0 unmask (enables) the corresponding data interrupt request, and write =1 masks (disables) the corresponding data interrupt request. |

## Status Interrupt Mask Register

While each timer may generate a status interrupt request, these requests are OR'ed to generate a single status interrupt signal to the System Event Controller. The `TIMER_STAT_IMSK` contains an interrupt mask for these requests, masking (disabling) or unmasking (enabling) the interrupts as programmed. The reset value of the `TIMER_STAT_IMSK` register is `0xFFFF`, masking these interrupts after reset.

**TIMER\_STAT\_IMSK: Status Interrupt Mask Register - R/W**

Reset = 0x00ff

**Figure 15-18:** TIMER\_STAT\_IMSK Register Diagram

**Table 15-30:** TIMER\_STAT\_IMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                    |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Status Interrupt Mask.<br>For all <code>TIMER_STAT_IMSK.TMRnn</code> bits, write =0 unmask (enables) the corresponding status interrupt request, and write =1 masks (disables) the corresponding status interrupt request. |

## Trigger Master Mask Register

As a trigger master, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_MSK` contains a trigger mask for these outputs, masking (disabling) or unmasking (enabling) the triggers as programmed. The reset value of the `TIMER_TRG_MSK` register is `0xFFFF`, masking these triggers after reset.

**TIMER\_TRG\_MSK: Trigger Master Mask Register - R/W**

Reset = `0x00ff`

**Figure 15-19:** TIMER\_TRG\_MSK Register Diagram

**Table 15-31:** TIMER\_TRG\_MSK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                      |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Trigger Output Mask.<br>For all <code>TIMER_TRG_MSK.TMRnn</code> bits, write =0 unmask (enables) the corresponding data trigger output, and write =1 masks (disables) the corresponding data trigger output. |

## Trigger Slave Enable Register

As a trigger slave, each timer can generate a unique data trigger pulse signal. The `TIMER_TRG_IE` contains trigger input enable bits for these signals, disabling or enabling the triggers as programmed. The reset value of the `TIMER_TRG_IE` register is `0xFFFF`, masking these triggers after reset.

TIMER\_TRG\_IE: Trigger Slave Enable Register - R/W

Reset = 0x0000

Figure 15-20: TIMER\_TRG\_IE Register Diagram

Table 15-32: TIMER\_TRG\_IE Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Trigger Input Enable.<br>For all TIMER_TRG_IE.TMRnn bits, write =0 disables the corresponding trigger input, and write =1 enables the corresponding trigger input. |

Data Interrupt Latch Register

The TIMER\_DATA\_ILAT holds the latched interrupt status for interrupt requests that have been unmasked (enabled) by the TIMER\_DATA\_IMSK register and generated according to the conditions selected by the TIMER\_TMRn\_CFG.IRQMODE bits. If a bit in TIMER\_DATA\_ILAT is already set and the corresponding interrupt is masked in TIMER\_DATA\_IMSK, the latch holds its old value, leaving the interrupt asserted until it is reset by software with a W1C operation.

Note that interrupt service routines (ISRs) should clear the appropriate bits in TIMER\_DATA\_ILAT before returning from the ISR, to ensure that the interrupt is not re-issued. To make sure that no timer event is missed, the latch should be reset at the very beginning of the ISR when in EXTCLK mode.

TIMER\_DATA\_ILAT: Data Interrupt Latch Register - R/W

Reset = 0x0000

Figure 15-21: TIMER\_DATA\_ILAT Register Diagram

**Table 15-33:** TIMER\_DATA\_ILAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Data Interrupt Latch.<br>For all <code>TIMER_DATA_ILAT.TMRnn</code> bits, status of =0 indicates no interrupt is latched, and status of =1 indicates a latched interrupt (indicating an unmasked interrupt request from a timer with a condition matching the one selected with corresponding <code>TIMER_TMRn_CFG.IRQMODE</code> bit has occurred). |

## Status Interrupt Latch Register

The `TIMER_STAT_ILAT` holds the latched interrupt status for error interrupts, indicating a timer overflow condition or indicating that prohibited programming has occurred for a timer. These interrupt status bits are sticky and are W1C. The bits in the `TIMER_STAT_ILAT` register provide information regarding each timer interrupt source.

**TIMER\_STAT\_ILAT: Status Interrupt Latch Register - R/W**

Reset = 0x0000

**Figure 15-22:** TIMER\_STAT\_ILAT Register Diagram

**Table 15-34:** TIMER\_STAT\_ILAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | TMRnn    | Status Interrupt Latch.<br>For all <code>TIMER_STAT_ILAT.TMRnn</code> bits, status of 0 indicates no error interrupt is latched, and status of 1 indicates a timer counter overflow or programming error interrupt is latched. |

## Error Type Status Register

The `TIMER_ERR_TYPE` contains Error Type status bits for each timer. These bits indicate the type of error (if any) in a running timer. This register is read-only. These status bits are cleared at reset and when a particular timer is enabled.

Each time an error interrupt is latched in `TIMER_STAT_ILAT`, the corresponding `TERRx` bits in `TIMER_ERR_TYPE` are loaded with a code that identifies the type of error that was detected. This status value is held until the next error or until a particular timer is restarted. No bus error is generated if a write is performed on `TIMER_ERR_TYPE`.

**TIMER\_ERR\_TYPE: Error Type Status Register - R/NW**

Reset = 0x0000 0000

**Figure 15-23:** `TIMER_ERR_TYPE` Register Diagram

**Table 15-35:** `TIMER_ERR_TYPE` Register Fields

| Bit No. | Bit Name | Description/Enumeration |                                       |

Broadcast Period Register

For timers with `TIMER_TMRn_CFG.BPEREN` enabled, a write to `TIMER_BCAST_PER` concurrently updates the period (`TIMER_TMRn_PER`) registers of only those timers. A read of `TIMER_BCAST_PER` returns `0x00000000`, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMRn_PER` register.

TIMER\_BCAST\_PER: Broadcast Period Register - R/WA

Reset = 0x0000 0000

Figure 15-24: TIMER\_BCAST\_PER Register Diagram

**Table 15-36:** TIMER\_BCAST\_PER Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Broadcast Period Value. |

## Broadcast Width Register

For timers with `TIMER_TMRn_CFG.BWIDEN` enabled, a write to `TIMER_BCAST_WID` concurrently updates the width (`TIMER_TMRn_WID`) registers of only those timers. A read of `TIMER_BCAST_WID` returns `0x00000000`, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMRn_WID` register.

### TIMER\_BCAST\_WID: Broadcast Width Register - R/WA

Reset = 0x0000 0000

**Figure 15-25:** TIMER\_BCAST\_WID Register Diagram

**Table 15-37:** TIMER\_BCAST\_WID Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Broadcast Width Value.  |

## Broadcast Delay Register

For timers with `TIMER_TMRn_CFG.BDLYEN` enabled, a write to `TIMER_BCAST_DLY` concurrently updates the delay (`TIMER_TMRn_DLY`) registers of only those timers. A read of `TIMER_BCAST_DLY` returns `0x00000000`, and no bus error is generated. To read back a written value, read that TMR's `TIMER_TMRn_DLY` register.

TIMER\_BCAST\_DLY: Broadcast Delay Register - R/WA

Reset = 0x0000 0000

Figure 15-26: TIMER\_BCAST\_DLY Register Diagram

Table 15-38: TIMER\_BCAST\_DLY Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Broadcast Delay Value.  |

Timer n Configuration Register

Each timer has a `TIMER_TMRn_CFG` register that specifies its operating mode. Only write to a `TIMER_TMRn_CFG` register when the corresponding timer is not running.

After disabling a timer operating in `PWMOUT` mode, verify that the timer has stopped running by checking the start/stop status of the timer in the `TIMER_RUN` register before writing to the timer's `TIMER_TMRn_CFG` register.

Note that a timer's `TIMER_TMRn_CFG` register may be read at any time.

**TIMER\_TMRn\_CFG: Timer n Configuration Register - R/W**

Reset = 0x0000

**Figure 15-27:** TIMER\_TMRn\_CFG Register Diagram

**Table 15-39:** TIMER\_TMRn\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration               |

## Timer n Counter Register

The `TIMER_TMRn_CNT` holds the current timer count. After enabling, the count is re-initialized to either 0x0 or 0x1, depending on the configuration and mode. The `TIMER_TMRn_CNT` is read only and may be read at any time (whether the timer is running or stopped). Reading `TIMER_TMRn_CNT` returns an atomic 32-bit value.

Depending on the timer operation mode, the counter increment can be clocked by a number of sources, including SCLK, the TMR or Alternate Capture input pins, `TMR_ALT_CLK0`, or `TMR_ALT_CLK1`. The counter retains its value after the timer is disabled.

# 16 Watchdog Timer (WDOG)

The processor includes a 32-bit timer for each core that can be used to implement a software watchdog function. A software watchdog can improve system reliability by generating an event to the processor core if the watchdog expires before being updated by software. The watchdog timers are clocked by the system clock (SCLK).

## WDOG Features

The watchdog timer has the following features.

- Two identical 32-bit watchdog timers
- 8-bit disable bit pattern
- Generates a general-purpose event for the core.

Typically, the watchdog timer is used to supervise stability of the system software. When used in this way, software reloads the watchdog timer in a regular manner so that the downward counting timer never expires (never becomes 0). An expiring timer then indicates that system software might be out of control. At this point based on the GP event generated by WDT, it is often better to reset and reboot the system using the Reset Control Unit.

For easier debugging, the watchdog timer does not decrement (even if enabled) when the processor is in emulation mode.

**NOTE:** The emulation event is controlled by the SDU (System Debug Unit). Please refer to the SDU chapter for more details on this.

## Watchdog Timer Functional Description

When enabled, the 32-bit watchdog timer counts downward every SCLK cycle. When the count becomes 0, the expiry event is generated. This generates an GP event to the processor. When the event is generated, the core and the peripherals need to be reset using the software. The counter value can be read through the 32-bit WDOG\_STAT register. The WDOG\_STAT register cannot, however, be written directly. Rather, software writes the watchdog period value into the 32-bit WDOG\_CNT register before the watchdog is enabled. Once the watchdog is started, the period value cannot be altered.

WDOG Register List

Table 16-1: WDOG Module Registers

| Name      | Description                    |
|-----------|--------------------------------|
| WDOG_CTL  | Control Register               |
| WDOG_CNT  | Count Register                 |
| WDOG_STAT | Watchdog Timer Status Register |

| WDOG1 Expiration | 3  |             | LEVEL       |

WDOG Block Diagram

The figure below shows the detailed watchdog timer block diagram.

Watchdog Timer Block Diagram

## Internal Interface

The watchdog timer does not directly interact with any pins of the chip.

## External Interface

The watchdog timer is clocked by the system clock (SCLK) and its registers are accessed through the 16-bit peripheral MMR access bus. The 32-bit WDOG\_CNT and WDOG\_STAT registers must always be accessed by 32-bit read/write operations. Hardware ensures that those accesses are atomic. When the counter expires, the GP expiry event is generated.

## WDOG Configuration

### *PREREQUISITE:*

To start the watchdog timer, use the following procedure

1. Set the count value for the watchdog timer by writing the count value into the Watchdog Count register (WDOG\_CNT). Note that loading the WDOG\_CNT register while the timer is not enabled also pre-loads the WDOG\_STAT register.
2. Enable the watchdog timer by writing to the WDOG\_CTL.WDEN bit field. The watchdog timer then begins counting down, decrementing the value in the WDOG\_STAT register. When the WDOG\_STAT reaches 0, the expiry event is generated.

*ADDITIONAL INFORMATION:* To prevent the event from being generated, software must reload the count value from the WDOG\_CNT register to the WDOG\_STAT register by executing a write (of any value) to WDOG\_STAT, or must disable the watchdog timer in the WDOG\_CTL register before the watchdog timer expires.

- a. If software does not serve the watchdog in time, the WDOG\_STAT register continues decrementing until it reaches 0. When watchdog decrements and reaches 0, it generates a GP interrupt if enabled and the software can perform core and/or system reset.

*ADDITIONAL INFORMATION:* Once the counter stops reaches 0, it stops decrementing and remains at 0. Additionally, the WDRO latch bit in the WDOG\_CTL register is set.

- b. If the watchdog is enabled with a zero value loaded to the counter and the WDRO bit was cleared, the WDRO bit of the watchdog control register is set immediately and the counter remains at zero without further decrements. If, however, the WDRO bit was set by the time the watchdog is enabled, the counter decrements to 0xFFFF FFFF and continues operation.

*ADDITIONAL INFORMATION:* Software can disable the watchdog timer only by writing a 0xAD value (WDDIS) to the WDEN field in the WDOG\_CTL register.

## WDOG Register Descriptions

Watch Dog Timer Unit (WDOG) contains the following registers.

**Table 16-3:** WDOG Module Registers

| Name      | Description                    |
|-----------|--------------------------------|
| WDOG_CTL  | Control Register               |
| WDOG_CNT  | Count Register                 |
| WDOG_STAT | Watchdog Timer Status Register |

### Control Register

The WDOG\_CTL register controls the watch dog timer. This register supports enabling/disabling the watch dog timer and supports checking the timer rollover status. Note that when the processor is in emulation mode, the watch dog timer counter will not decrement even if it is enabled.

**WDOG\_CTL: Control Register - R/W**

Reset = 0x0000 0ad0

|         |          | 1 WDT has expired                                                                                                                                                                                                                                                                               |
| 11:4    | WDEN     | Watch Dog Enable.<br>The WDOG_CTL.WDEN field is used to enable and disable the watch dog timer. Writing any value other than the disable value into this field enables the watch dog timer. This multi-bit disable key minimizes the chance of inadvertently disabling the watch dog timer.     |
|         |          | 173 Counter Disabled<br>All other values - counter enabled                                                                                                                                                                                                                                      |

## Count Register

The WDOG\_CNT register holds the programmable, unsigned count value. A valid write to this register also pre-loads the WDOG counter. For added safety, the WDOG\_CNT register can be updated only when the WDOG timer is disabled. A write to the WDOG\_CNT register while the timer is enabled does not modify the contents of this register. This register must be accessed with 32-bit read/writes only.

### WDOG\_CNT: Count Register - R/W

Reset = 0x0000 0000

**Figure 16-2:** WDOG\_CNT Register Diagram

**Table 16-5:** WDOG\_CNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | Count Value.            |

## Watchdog Timer Status Register

The WDOG\_STAT contains the current count value of the watch dog timer. Reads of this register return the current count value. When the watch dog timer is enabled, WDOG\_STAT is decremented by 1 on each SCLK cycle. When count value reaches 0, the watch dog timer stops counting, and the expiry event is generated. WDOG\_STAT is a 32-bit unsigned system MMR that must be accessed with 32-bit reads and writes.

Values cannot be stored directly in WDOG\_STAT, but are instead copied from the WDOG\_CNT register. This copy process can happen in two ways:

- While the watch dog timer is disabled, writing the WDOG\_CNT register pre-loads the WDOG\_STAT register.
- While the watch dog timer is enabled, writing the WDOG\_STAT register loads it with the value in WDOG\_CNT.

When the processor executes a write (of an arbitrary value) to WDOG\_STAT, the value in WDOG\_CNT is copied into WDOG\_STAT. Typically, software sets the value of WDOG\_CNT at initialization, then periodically writes to WDOG\_STAT before the watch dog timer expires. This reloads the watch dog timer with the value from WDOG\_CNT and prevents generation of the expiry event.

If the user does not reload the counter before SCLK\*Count register cycles, an expiry event is generated, and the WDOG\_CTL.WDRO bit is set. When this happens, the counter will stop decrementing and will remain at zero. If the counter is enabled with a zero loaded to the counter, the WDOG\_CTL.WDRO bit is set immediately and the counter remains at zero and does not decrement.

### WDOG\_STAT: Watchdog Timer Status Register - R/W

# 17 General-Purpose Counter (CNT)

The purpose of this interface is to convert pulses from incremental position encoders into data that is representative of the actual position. This is done by integrating (counting) pulses on one or two inputs. Since integration provides relative position, some devices also feature a zero position input (zero marker) that can be used to establish a reference point to verify that the acquired position does not drift over time. In addition, the incremental position information can be used to determine speed, if the time intervals are measured. The GP counter provides flexible ways to establish position information. When used in conjunction with the GP timer block, the GP counter may allow for the acquisition of coherent position/time-stamp information that enables speed calculation.

## CNT Features

The GP Counter includes the following features:

- 32-bit up/down counter
- Quadrature encode mode (Gray code)
- Binary encoder mode
- Alternative frequency-direction mode
- Timed direction and up/down counting modes
- Zero marker/push button support
- Capture event timing in association with GP Timer
- Boundary comparison and boundary setting features

## CNT Functional Description

A block diagram of the GP counter is shown below. The CUD and CDG pins accept various forms of incremental inputs and are processed by the 32-bit counter, while the CZM pin can be used to sense the pressing of a push button.

**NOTE:** When enabled, the GP counter requires 3 SCLK cycles of initialization before recognizing valid toggles on its input pins.

The three input pins may be filtered (debounced) before being evaluated by the GP counter.

The GP counter also features a flexible boundary comparison. In all of the operating modes, the counter can be compared to an upper and lower limit. A variety of actions can be taken when these limits are reached.

The module can optionally generate an interrupt request to the system through its IRQ line. On many processors, there is also an output that can be used by a GP Timer module to generate time-stamps on certain events.

CNT Register List

The counter (CNT) provides support for manually controlled rotary controllers, such as the volume wheel on a radio device. This unit also supports industrial encoders.

The CNT converts pulses from incremental position encoders into data that is representative of the actual position. To complete this task, the CNT integrates (counting) pulses on one or two inputs. Because integration provides relative position, some devices also feature a zero position input (zero marker) that establishes a reference point, verifying that the acquired position does not drift over time. The incremental position information may also be used to determine speed, if the time intervals are measured. The CNT provides flexible ways to establish position information. When used in with the , the CNT allows acquisition of coherent position/time-stamp information, enabling speed calculation.

A set of registers govern CNT operations. For more information on CNT functionality, see the CNT register descriptions.

**Table 17-4:** Slaves ADSP-BF60x CNT Trigger List

| Description | ID | Sensitivity |
|-------------|----|-------------|
|             |    |             |

## CNT Operating Modes

The GP counter has the following five modes of operation.

- 1. Quadrature Encoder
- 2. Binary Encoder
- 3. Up/Down Counter
- 4. Direction Counter
- 5. Timed Direction

With the exception of the timed direction mode, the GP counter can operate with the GP timer block to capture additional timing information (time-stamps) associated with events detected by this block.

### Quadrature Encoder Mode

In this mode, the CUD: CDG inputs expect a quadrature-encoded signal that is interpreted as a two-bit Gray code. The order of transitions of the CUD and CDG inputs determines whether the counter increments or decrements. The CNT\_CNTR register contains the number of transitions that have occurred. Refer to the table below for more details. Optionally, an interrupt is generated if both inputs change within one SCLK cycle. Such transitions are not allowed by Gray coding. Therefore, the CNT\_CNTR register remains unchanged, and an error condition is signaled.

**Table 17-5:** Quadrature Events and Counting Mechanism

| CNT_COUNTER<br>Register Value | -4 | -3 | -2 | -1 | 0  | +1 | +2 | +3 | +4 |
|-------------------------------|----|----|----|----|----|----|----|----|----|
| CDG:CUD Inputs                | 00 | 01 | 11 | 10 | 00 | 01 | 11 | 10 | 00 |

It is possible to reverse the count direction of the Gray coded signal. This can be achieved by enabling the polarity inverter of either the CUD pin or the CDG pin. Inverting both pins does not alter the behavior. This feature can be enabled with the CDGINV and CUDINV bits in the CNT\_CFG register.

As an example, if the CDG: CUD inputs are 00 respectively, and the next transition is to 01, this would normally increment the counter as is shown in the table. If the CUD polarity is inverted, this generates a received input of 01 followed by 00. This results in a decrement of the counter, altering the behavior of the connected hardware.

### Binary Encoder Mode

This mode is almost identical to quadrature encoder mode, with the exception that the CUD: CDG inputs expect a binary-encoded signal. The order of transitions of the CUD and CDG inputs determines whether the

counter increments or decrements. The CNT\_CNTR register contains the number of transitions that have occurred. Refer to Table 2. Optionally, an interrupt is generated if the detected code steps by more than 1 (in binary arithmetic) within one SCLK cycle. Such transitions are considered erroneous. Therefore, the CNT\_CNTR register remains unchanged, and an error condition is signaled.

**Table 17-6:** Binary Events and Counting Mechanism

| CNT_COUNTER Register Value | -4 | -3 | -2 | -1 | 0  | +1 | +2 | +3 | +4 |
|----------------------------|----|----|----|----|----|----|----|----|----|
| CDG:CUD Inputs             | 00 | 01 | 10 | 11 | 00 | 01 | 10 | 11 | 00 |

Reversing the CUD and CDG pin polarity has a different effect for the binary encoder mode than for the quadrature encoder mode. Inverting the polarity of the CUD pin only, or inverting both the CUD and CDG pins, results in reversing the count direction.

## Up/Down Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the input pins. If an active edge is detected at the CUD input, the counter increments. The active edge can be selected by the CNT\_CFG.CUDINV bit. If an active edge is detected at the CDG input, the counter decrements. The active edge can be selected by the CNT\_CFG.CDGINV bit. If simultaneous edges occur on CDG and CUD pins, the counter remains unchanged, and both up-count and down-count events are signaled in the CNT\_STAT register.

## Direction Counter Mode

In this mode, the counter is incremented or decremented at every active edge of the CDG input pin. The state of the CUD input determines whether the counter increments or decrements. The polarity can be selected by the CNT\_CFG.CUDINV bit. If an active edge is detected at the CDG input, the counter value changes by one in the selected direction. The active edge can be selected by the CNT\_CFG.CDGINV bit.

## Timed Direction Mode

In this mode, the counter is incremented or decremented at each SCLK cycle. The state of the CUD input determines whether the counter increments or decrements. The polarity can be selected by the CNT\_CFG.CUDINV bit. The CDG pin can be used to gate the clock. The polarity can be selected by the CNT\_CFG.CDGINV bit.

## CNT Event Control

Eleven events can be signaled to the processor using status information and optional interrupt requests. The interrupts are enabled by the respective bits in the CNT\_IMSK register. Dedicated bits in the CNT\_STAT register report events. When an interrupt from the GP counter is acknowledged, the application software

is responsible for correct interpretation of the events. It is recommended to logically AND the content of the `CNT_IMSK` and `CNT_STAT` registers to identify pending interrupts. Interrupt requests are cleared by write-one-to-clear (W1C) operations to the `CNT_STAT` register. Hardware does not clear the status bits automatically, unless the counter module is disabled.

## Illegal Gray/Binary Code Events

When illegal transitions occur in quadrature encoder or binary encoder modes, the `CNT_STAT.ICII` bit is set. If enabled by the `CNT_IMSK.ICIE` bit, an interrupt request is generated. The `ICIE` bit should only be set in the quadrature encoder or binary encoder modes.

## Up/Down Count Events

The `UCII` bit in the `CNT_STAT` register indicates whether the counter has been incremented. Similarly, the `DCII` bit reports decrements. The two events are independent. For instance, if the counter first increments by one and then decrements by two, both bits remain set, even though the resulting counter value shows a decrement by one.

In up/down counter mode, hardware may detect simultaneous active edges on the `CUD` and `CDG` inputs. In that case, the `CNT_CNTR` remains unchanged, but both the `UCII` and `DCII` bits are set. Interrupt requests for these events may be enabled through the `UCIE` and `DCIE` bits. This feature should be used carefully when the counter is clocked at high rates. This is especially critical when the counter operates in `DIR_TMR` mode, as interrupts would be generated every `SCLK` cycle. These events can also be used for additional push buttons, if GP counter features are not needed. When up/down counter mode is enabled, these count events can be used to report interrupts from push buttons that connect to the `CUD` and `CDG` inputs.

## Zero-Count Events

The `CZEROII` status bit indicates that the `CNT_CNTR` has reached a value equal to `0x0000 0000` after an increment or decrement. This bit is not set when the counter value is set to zero by a write to `CNT_CNTR` or by setting the `W1LCNT_ZERO` bit in the `CNT_CMD` register. If enabled by the `CZEROIE` bit, an interrupt request is generated.

## Overflow Events

There are two status bits that indicate whether the signed counter register has overflowed from a positive to a negative value or vice versa. The `COV31II` bit reports that the 32-bit `CNT_COUNT` register has either incremented from `0x7FFF FFFF` to `0x8000 0000`, or decremented from `0x8000 0000` to `0x7FFF FFFF`. If enabled by the `COV31IE` bit, an interrupt request is generated. Similarly, in applications where only the lower 16 bits of the counter are of interest, the `COV15II` status bit reports counter transitions from `0xFFFF 7FFF` to `0xFFFF 8000`, or from `0xFFFF 8000` to `0xFFFF 7FFF`. If enabled by the `COV15IE` bit, an interrupt request is generated.

## Boundary Match Events

The MINCII and MAXCII status bits report boundary events as described in TBD. These bits are not set if the CNT\_CNTR, CNT\_MAX, or CNT\_MIN registers are updated by software or the CNT\_CMD register is written to. The MINCIE and MAXCIE bits in the CNT\_IMSK register enable interrupt generation on boundary events.

## Zero Marker Events

There are three status bits; CZMII, CZMEII and CZMZII associated with zero marker events, as described in TBD. Each of these events can optionally generate an interrupt request, if enabled by the corresponding CZMIE, CZMEIE and CZMZIE bits in the CNT\_IMSK register.

## CNT Programming Model

The following sections provide information used to assist in programming the interface.

### CNT General Programming Flow

The following are general guidelines for configuring and enabling the GP Counter.

1. Initialize (but do not enable) the GP Counter for the desired mode and settings via the CNT\_CFG register.
2. Usually, events of interest are processed using interrupts rather than by polling status bits. If this is the case, clear all status bits and activate the generation of interrupt requests with the CNT\_IMSK register.
3. Configure interrupts at the system level, to insure desired interrupt signalling to the system event controller.
4. If timing information is required, set up the relevant GP Timer in Width Capture mode.
5. Finally, enable interrupts and the GP Counter itself via the CNT\_IMSK and CNT\_CFG registers, respectively.

### CNT Mode Configuration

The CZM input pin can be used to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes: push-button mode, zero-marker-zeros-counter mode, zero-marker-error mode, and zero-once mode.

## Configuring GP Counter Push-button Operation

The `CZM` input pin can be used to sense the zero marker output of a rotary device or to detect the pressing of a push button. There are four programming schemes, which are functional in all counter modes: push-button mode, zero-marker-zeros-counter mode, zero-marker-error mode, and zero-once mode.

1. Set `CNT_IMSK.CZME` to enable (unmask) the Zero Marker Error interrupt.
2. Select the active edge polarity through the `CNT_CFG.CZMINV` bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

Now, an active edge at the `CZM` input sets the `CNT_STAT.CZME` bit.

## Configuring Zero-Marker-Zeros-Counter Mode

The following provides information on configuring Zero-Marker-Zeros-Counter mode for the GP Counter.

1. Set `CNT_IMSK.CZMZ` to enable `CNT_CNTR` to be zeroed by a Zero Marker interrupt.
2. Set `CNT_CFG.ZMZC` to enable `ZMZC` mode.
3. Select the active edge polarity through the `CNT_CFG.CZMINV` bit.
4. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

This causes an active level at the `CZM` pin to clear the `CNT_CNTR` register and keep it cleared until the `CZM` pin is deactivated. In addition, the `CNT_STAT.CZMZ` bit is set.

## Configuring Zero-Marker-Error Mode

This mode is used to detect discrepancies between counter value and the zero marker output of certain rotary encoder devices.

1. Set the `CNT_IMSK.CZMEIE` bit to enable this mode.
2. Select the active edge of the `CZM` pin through the `CNT_CFG.CZMINV` bit.
3. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

When an active edge is detected at the `CZM` input pin, the four LSBs of the `CNT_CNTR` register are compared to zero. If they are not zero, a mismatch is signaled by way of the `CNT_STAT.CZMEII` bit.

## Configuring Zero-Once Mode

This mode is used to perform an initial reset of the counter value when an active zero marker is detected. After that, the zero marker is ignored (the counter is not reset anymore).

1. Set the `CNT_CMD.W1ZMONCE` bit to enable this mode.
2. Select the active edge of the `CZM` pin through the `CNT_CFG.CZMINV` bit.
3. Ensure that at least one of the following `CNT_IMSK` bits is enabled: `CZM`, `CZME`, `CZMZ`
4. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

The `CNT_CNTR` register and the `W1ZMONCE` bit are cleared on the next active edge of the `CZM` pin. Now the `W1ZMONCE` bit can be read to check whether the event has already occurred, if desired.

## Configuring Boundary Auto-Extend Mode

In this mode, the boundary registers (`CNT_MIN` and `CNT_MAX`) are modified by hardware whenever the `CNT_CNTR` value reaches either of them. This mode is useful, for example, to keep track of the widest angle a thumbwheel ever reported, even if the software did not generate interrupts.

1. Initialize `CNT_CNTR` with the desired value.
2. Set both `CNT_MIN` and `CNT_MAX` to this same value.
3. Configure the `CNT_CFG.BNDMODE` field for Auto Extend mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

The `CNT_MAX` register is loaded with the current `CNT_CNTR` value if the latter increments beyond the `CNT_MAX` value. Similarly, the `CNT_MIN` register is loaded with the `CNT_CNTR` value if the latter decrements below the `CNT_MIN` value. The `CNT_STAT.MAXCII` and `CNT_STAT.MINCII` status bits are set when the `CNT_CNTR` value matches the respective boundary register value.

## Configuring Boundary Capture Mode

In this mode, the `CNT_CNTR` value is latched into the `CNT_MIN` register at one detected edge of the `CZM` input pin, and latched into `CNT_MAX` at the opposite edge.

1. To capture the `CZM` pin rising edge into `CNT_MIN` and the falling edge into `CNT_MAX`, program `CNT_CFG.CZMINV` for active high polarity. Conversely, to capture the `CZM` pin falling edge into `CNT_MIN` and the rising edge into `CNT_MAX`, program `CNT_CFG.CZMINV` for active low polarity.

2. Program the `CNT_IMSK.MAXCIE` and `CNT_IMSK.MINCIE` interrupt mask bits according to interrupt generation requirements.
3. Configure the `CNT_CFG.BNDMODE` field for Boundary Capture mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

The `CNT_STAT.MAXCII` and `CNT_STAT.MINCII` status bits report the capture event, depending on how interrupt masks are configured.

## Configuring Boundary Compare and Boundary Zero Modes

In these modes, the two boundary registers (`CNT_MAX` and `CNT_MIN`) are simply compared to the value in the `CNT_CNTR` register.

1. Program `CNT_MAX` and `CNT_MIN` registers with appropriate upper and lower range values.
2. Program the `CNT_IMSK.MAXCIE` and `CNT_IMSK.MINCIE` interrupt mask bits according to interrupt generation requirements.
3. Configure the `CNT_CFG.BNDMODE` field for Boundary Compare mode.
4. Proceed with any other desired configuration steps and enable the peripheral.

*RESULT:*

If after incrementing, `CNT_CNTR` equals `CNT_MAX`, then the `CNT_STAT.MAXCII` bit is set. Similarly if after decrementing, `CNT_CNTR` equals `CNT_MIN`, then the `CNT_STAT.MINCII` bit is set. Additionally, for Boundary Zero mode, the counter value in `CNT_CNTR` is set to zero. Note that the `MAXCII` and `MINCII` bits are not set if the `CNT_MAX` and/or `CNT_MIN` registers are updated by software.

## CNT Programming Concepts

Using the features, operating modes, and event control for the GP Counter to their greatest potential requires an understanding of some GP Counter-related concepts. Some key aspects to consider are input noise filtering and capturing timing information.

### CNT Input Noise Filtering

In all modes, the three input pins can be filtered to present clean signals to the GP counter logic. This filtering can be enabled or disabled by the `CNT_CFG.DEBE` bit. The following figure shows the filtering operation for the `CUD` pin.

**Figure 17-1:** Programmable Noise Filtering

The filtering mechanism is implemented using counters for each GP counter pin, where each counter is initialized from the `CNT_DEBNCE.DPRESCALE` field. When a transition is detected on a pin, the corresponding counter starts counting up to the programmed number of `SCLK` cycles. The state of the pin is latched after time  $T_{\text{filter}}$  and passed on to the GP counter logic.

The time  $t_{\text{filter}}$  is determined, given `SCLK` and the `CNT_DEBNCE.DPRESCALE` value, by the following formula, where lower values of `DPRESCALE` result in shorter debounce delays:

$$t_{\text{filter}} = 128 \times (2^{\text{DPRESCALE}} \times \text{SCLK})$$

## Capturing Counter Interval and CNT\_CNTR Read Timing

When the count speed is very low, it is often useful to capture the time elapsed since the last count event. In order to do this, program the associated GP Timer's `TMR_CFG` register in a Width Capture mode with `PULSEHI = 0`, `TMODE=b#1011` and `TINSEL = 1`.

**Figure 17-2:** Capture Intervals

The following figure shows the operation of the GP counter and the GP timer in this mode.

The TO signal generates a pulse every time a count event occurs. In addition, when the processor reads the CNT\_CNTR register, the TO signal presents a pulse which is extended (high) until the next count event. The GP timer updates its TMR\_PER register with the period (measured from falling edge to falling edge, because PULSEHI = 0) of the TO signal. The TMR\_WID register is updated with the pulse width (the portion where TO is low, again because PULSEHI = 0). Both registers are updated at every rising edge of the TO signal (because TMR\_CFG.TMODE=b#011).

Therefore, the TMR\_PER register contains the period between the last two count events, and the TMR\_WID register contains the time since the last count event and the read of the CNT\_CNTR register, both measured in SCLK cycles.

Read the CNT\_CNTR register to latch the two time measurements, providing a coherent triplet of information to calculate speed and position.

**NOTE:** Speed restrictions apply to the use of the T0 signal. Therefore, the user must take care to not operate at very high count event rates. For instance, if CNT\_CNTR is incremented/decremented every SCLK cycle (timed direction mode), the T0 signal will not be valid.

## Capturing Time Interval Between Successive Counter Events

When the only timing information of interest is the interval between successive count events, the associated timer should be programmed in a width capture mode with TMR\_CFG bit settings of PULSEHI = 1, TMODE=b#1010 and TINSEL = 1. Typically, this information is sufficient if the speed of GP counter events is known not to reach very low values.

### Figure 17-3: Period Register Timing

The figure above shows the operation of the GP Counter and the GP timer in this mode. The T0 signal generates a pulse every time a count event occurs. The GP timer updates its TMR\_PER register with the period (measured from rising edge to rising edge) of the T0 signal. The TMR\_PER register is updated at every rising edge of the T0 signal and contains the number of SCLK cycles that have elapsed since the previous rising edge.

Incidentally, the TMR\_WID register is also updated at the same time, but is generally of no interest in this mode of operation. If no reads of the CNT\_CNTR register occur between counter events, the TMRn\_WID register only contains the width of the T0 pulse. If a read of CNT\_CNTR has occurred between events, the TMR\_WID register contains the time between the read of CNT\_CNTR and the next event.

This mode can also be used with `PULSEHI = 0`. In this case, the period of `T0` is measured between falling edges. It results in the same values as in the previous case, only the latching occurs one `SCLK` cycle later.

## CNT Register Descriptions

CNT (CNT) contains the following registers.

**Table 17-7:** CNT Module Registers

| Name       | Description             |
|------------|-------------------------|
| CNT_CFG    | Configuration Register  |
| CNT_IMSK   | Interrupt Mask Register |
| CNT_STAT   | Status Register         |
| CNT_CMD    | Command Register        |
| CNT_DEBNCE | Debounce Register       |
| CNT_CNTR   | Counter Register        |
| CNT_MAX    | Maximum Count Register  |
| CNT_MIN    | Minimum Count Register  |

### Configuration Register

The `CNT_CFG` register configures counter modes, configures input pins, and enable the CNT.

**CNT\_CFG: Configuration Register - R/W**

Reset = 0x0000

**Figure 17-4:** CNT\_CFG Register Diagram

**Table 17-8:** CNT\_CFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                           |

## Interrupt Mask Register

The CNT\_IMSK register supports enabling (unmasking) interrupt request generation from each of the CNT events.

All bits in CNT\_IMSK either disable/mask an interrupt (if bit cleared) or enable/unmask an interrupt (if bit set).

CNT\_IMSK: Interrupt Mask Register - R/W

Reset = 0x0000

## Status Register

The CNT\_STAT register provides status information for each of the CNT events. When a CNT event is detected, the corresponding bit in this register is set. It remains set until either software writes a "1" to the bit (write-1-to-clear) or the CNT is disabled.

All bits in CNT\_STAT indicate either no interrupt pending (if bit cleared) or an interrupt pending (if bit set).

**CNT\_STAT: Status Register - R/W**

Reset = 0x0000

**Figure 17-6:** CNT\_STAT Register Diagram

**Table 17-10:** CNT\_STAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                  |
|---------|----------|------------------------------------------|
| 10      | CZMZ     | Counter Zeroed By Zero Marker interrupt. |
| 9       | CZME     | Zero Marker Error interrupt.             |

| Bit No. | Bit Name | Description/Enumeration             |
|---------|----------|-------------------------------------|
| 2       | DC       | Downcount interrupt.                |
| 1       | UC       | Upcount interrupt.                  |
| 0       | IC       | Illegal gray/binary code interrupt. |

## Command Register

The `CNT_CMD` register configures the CNT, enabling operations such as zeroing a counter register and copying or swapping boundary registers. These actions are taken by setting the appropriate bit.

Read operations from this register do not return meaningful values, with the exception of the `CNT_CMD.W1ZMONCE` bit, where a set bit indicates that:

the bit has been set by software before, but

no zero marker event has been detected on the `CNT_ZM` pin yet.

For more information, see the CNT functional description.

The `CNT_CNTR`, `CNT_MIN`, and `CNT_MAX` registers can be initialized to zero by setting the `CNT_CMD.W1LCNTZERO`, `CNT_CMD.W1LMINZERO`, and `CNT_CMD.W1LMAXZERO` bits. In addition to clearing registers, `CNT_CMD` permits modifying the `CNT_MIN` and `CNT_MAX` boundary registers in a number of ways. The current counter value in `CNT_CNTR` can be captured and loaded into either of the two boundary registers to create new boundary limits. This operation is performed by setting the `CNT_CMD.W1LMAXCNT` and `CNT_CMD.W1LMINCNT` bits. Alternatively, the counter can be loaded from `CNT_MAX` or `CNT_MIN` using the `CNT_CMD.W1LCNTMAX` and `CNT_CMD.W1LCNTMIN` bits. It is also possible to transfer the current `CNT_MAX` value into `CNT_MIN` (or vice versa) through the `CNT_CMD.W1LMINMAX` and `CNT_CMD.W1LMAXMIN` bits.

Another counter operation is the ability to only have the zero marker clear the `CNT_CNTR` register once. For more information, see the CNT functional description.

It is possible for multiple actions to be performed simultaneously by setting multiple bits in the `CNT_CMD` register, but there are restrictions. The bits associated with each command have been grouped together such that all bits that involve a write to the `CNT_CNTR`, `CNT_MAX`, or `CNT_MIN` are located within bits 4-bit groups of the `CNT_CMD` register.

Note that a maximum of three commands can be issued at any one time, excluding the `CNT_CMD.W1ZMONCE` command. Also note that `CNT_CMD.W1LCNTMIN`, `CNT_CMD.W1LCNTMAX`, and `CNT_CMD.W1LCNTZERO` bits have to be used exclusively. Never set more than one of them at the same time.

**CNT\_CMD: Command Register - R/WA**

| 5       | W1LMINCNT  | Write 1 MIN capture from CNTR.                                                                                                                                                                                                                                     |
| 4       | W1LMINZERO | Write 1 MIN to zero.                                                                                                                                                                                                                                               |
| 3       | W1LCNTMAX  | Write 1 CNTR load from MAX.                                                                                                                                                                                                                                        |
| 2       | W1LCNTMIN  | Write 1 CNTR load from MIN.                                                                                                                                                                                                                                        |
| 0       | W1LCNTZERO | Write 1 CNTR to zero.                                                                                                                                                                                                                                              |

## Debounce Register

The CNT\_DEBNCE register selects the noise filtering characteristic of the three input pins according to the formula:

$$t_{\text{filter}} = 128 \times (2^{\text{DPRESCALE}} / \text{SCLK})$$

**CNT\_DEBNCE: Debounce Register - R/W**

Reset = 0x0000

## Counter Register

The CNT\_CNTR register holds the 32-bit, twos-complement count value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows use of the CNT as a 16-bit counter if sufficient for the application.

CNT\_CNTR: Counter Register - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | VALUE    | CNTR Value.             |

## Maximum Count Register

The CNT\_MAX register holds the 32-bit, twos-complement, higher boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

| 31:0    | VALUE    | MAX Value.              |

## Minimum Count Register

The CNT\_MIN register holds the 32-bit, twos-complement, lower boundary value. It can be read and written at any time. Hardware ensures that reads and write are atomic, by providing respective shadow registers. This register can be accessed with either 32-bit or 16-bit operations. This allows for using the CNT as a 16-bit counter if sufficient for the application.

# 18 Pulse-Width Modulator (PWM)

The Pulse Width Modulator (PWM) module is a flexible and programmable waveform generator. With minimal CPU intervention the PWM peripheral is capable of generating complex waveforms for motor control, Pulse Coded Modulation (PCM), Digital to Analog Conversion (DAC) functionality, power switching and power conversion. The PWM module has 4 PWM pairs capable of 3-phase PWM generation for source inverters for AC induction and DC brush less motors.

## PWM Features

The two 3-phase PWM generation units each feature:

- 16-bit center-based PWM generation unit
- Programmable PWM pulse width
- Single/double update modes
- Programmable dead time and switching frequency
- Twos-complement implementation which permits smooth transition to full ON and full OFF states
- Dedicated asynchronous PWM shutdown signal

## PWM Register List

The pulse-width modulator (PWM) includes multiple timers (providing period flexibility) and channels (provide mode, interrupt, and pulse shape flexibility), permitting a wide variety of PWM output options for motor control and other applications. A set of registers govern PWM operations. For more information on PWM functionality, see the PWM register descriptions.

## Functional Description

Each PWM Module has 4 PWM pairs with 2 outputs: a high and a low side signal.

During initialization, the `PWM_TMR` register is written to define the PWM period, and the Channel Pulse Duty registers are written to define the initial channel pulse widths. The `PWM_CTL` and `PWM_CHANCFG` registers are written, depending on the system configuration and modes. The `PWM_STAT` register can be read to determine polarity, and whether switched reluctance (SR) mode (`PWM_SR` bit) is enabled, and whether an external trip situation is preventing the correct start-up of the PWM Controller. An active external trip event must be resolved prior to PWM startup. The `PWM_CTL` register is then written to define the major operating mode and to enable the PWM outputs and PWM sync pulse.

During the `PWM_SYNCINT` interrupt driven control loop, only the `PWM_AH0.DUTY` values are updated typically.

Typically the `PWMx_TMR` interrupt is used to periodically execute an Interrupt Service Routine (ISR), to update the PWM channel control and duty registers according to a control algorithm based on expected operation and sampled existing operation. The `PWMx_TMR` interrupt also can trigger an ADC to sample data for use during the ISR.

During processor boot the PWM is initialized and the program flow enters a wait loop. When a `PWM_SYNC` interrupt occurs, the ADC samples data, the data is algorithmically interpreted, and new PWM channel duties are calculated and written to the PWM. More sophisticated implementations include

different startup, runtime, and shutdown algorithms to determine PWM channel duties based on expected behavior and further features.

During initialization, the `PWM_TMO` registers are written to define the PWM periods of different timers. The `PWM_DLYA` registers are written to define the initial phase difference between the main timer and the other timers. The `PWM_CHANCFG` and `PWM_ACTL` registers are written to define the initial pulse configuration. The Channel x High/Low Duty registers are programmed to define the initial duty values. The requisite dead-time must be written into the `PWM_DT` register. The `PWM_CTL` register is written in the end with the final configurations and enable bit for the entire PWM (`PWM_CTL.GLOBEN`).

The `PWM_SYNC` interrupt is assigned to one of the core's user interrupts. During the `PWM_SYNC` interrupt driven control loop, only the `PWM_DLYA`, the duty registers and channel C high pulse duty register values are typically updated. To see programming limitations on the PWM registers, see the Register Descriptions section.

During any external trip event (if not disabled), the PWM outputs will be turned off. When a PWM output is turned off, it means that the output level is held at a polarity opposite that given in the `PWM_CHANCFG.POLDH` bits in the `PWM_CHANCFG` register. The PWM sync pulse will continue to operate if it is already enabled. A `PWMTRIP` interrupt occurs if unmasked, to notify the software of this event.

Note that even if the clock to the PWM is damaged, an external trip event will turn off the PWM outputs, but the `PWMTRIP` interrupt may not occur.

## Architectural Concepts

The PWM Controller is driven by a clock, whose period is  $t_{SCLK}$ . The PWM generator produces four pairs (four high-side and four low-side) of PWM signals on the eight PWM output pins. Each high and low pair constitutes a channel. For example `PWM_AL/PWM_AH` make up channel A, and `PWM_BLPWM_BH` make up channel B and so on. Each pair of channel outputs can be produced with reference to either a main timer or to an independent timer. These timers operate on a switching frequency determined by the `PWM_TMO` registers. There are 2 duty registers for every PWM output, which enable generation of symmetrical or asymmetrical waveforms that produce lower harmonic distortion in three-phase PWM inverters, with minimal CPU intervention.

## Block Diagram

The following figure shows a block diagram that represents the main functional blocks of the PWM controller.

**Figure 18-1: PWM Block Diagram**

The primary blocks are described below.

- Each pair of PWM signals is referenced either to the main timer or to the independent timer.
- PWMTMR0 is the main timer and can trigger the delayed start of the other timers.
- Timing Control Units, one for each channel, which together form the core of the PWM, generate the required complex waveforms on the high side and low side outputs for the respective channel.
- Dead Time insertion is done after the ideal PWM output pair is generated.
- The Gate Drive Unit generates the high-frequency chopping signal and subsequently mixes it with the requisite PWM output signals.
- The PWM Shutdown and Interrupt Controller manages the various PWM shutdown modes for the timing unit and generates the requisite interrupt signals.
- The PWM Sync Pulse Control Unit generates the internal PWM\_SYNC pulse and also controls whether the external PWM\_SYNC input pulse is used.

## Timer Units

Five timers make up the time base for the PWM module. The main timer, PWMTMR0 operates at a switching frequency determined by the period register PWM\_TM0. The four remaining timers PWMTMR1,

PWMTMR2, PWMTMR3 and PWMTMR4 can operate at independent switching frequencies determined by their respective registers.

These four timers can be programmed to work at a multiple of the main timer's frequency by programming respective PWM\_TMx appropriately. In this case, the PWM\_DLYA registers can be used to provide for lead-lag phase control of a given timer with respect to the main timer PWMTMR0.

**NOTE:** When delayed operation of a timer is enabled, its register value must either be equal to the PWM\_TMO register value or PWM\_TMO must be an integer multiple of each timer's register to ensure proper function. Non-integer multiples are not allowed.

## PWM Switching Frequency (PWM\_TM) Register

The 16-bit read/write PWM period register controls the PWM switching frequency. The fundamental timing unit of the PWM Controller is  $t_{SCLK}$ . Therefore, for a 100 MHz system clock (SCLK),  $f_{SCLK}$ , the fundamental time increment ( $t_{SCLK}$ ) is 10 ns. The value written to a timer's register is effectively the number of  $t_{SCLK}$  clock increments in half a PWM period. The required timer register value as a function of the desired PWM switching frequency ( $f_{PWM}$ ) is given by:

$$PWM\_TM = f_{SCLK} / 2 \times f_{PWM}$$

Therefore, the PWM switching period ( $T_s$ ) can be written as:

$$T_s = 2 \times PWM\_TM \times t_{SCLK}$$

For example, for an  $f_{SCLK}$  of 100 MHz and a desired PWM switching frequency ( $f_{PWM}$ ) of 10 kHz ( $T_s = 100$  ms), the correct value to load into the timer register is:

$$PWM\_TM = 100 \times 10^6 \div 2 \times 10 \times 10^3 = 5000$$

The largest value that can be written to the 16-bit timer register is 0xFFFF = 65,535, which, at an  $f_{SCLK}$  of 100 MHz, corresponds to a minimum PWM switching frequency of:

$$f_{PWM(min)} = 100 \times 10^6 \div 2 \times 65535 = 762 \text{ Hz}$$

**NOTE:** Timer register values of 0 and 1 are not defined and should not be used when the PWM outputs or PWM is enabled.

## Timer Unit Operation

The PWM timer is an up-down counter operates on the peripheral clock of period  $t_{CK}$ . The period of the PWM timer is divided into two halves. In the first half, the timer roughly counts down from  $PWM\_TMx/2$  to  $-PWM\_TMx/2$ . During this half, the PWM\_STAT.TMR0PHASE register is held at 0. In the second half of the period, the timer roughly counts up from  $-PWM\_TMx/2$  to  $PWM\_TMx/2$ . The PWM\_STAT.TMR0PHASE bit indicates a 1 during this half.

The actual partition of the periods varies slightly between odd and even values of the half-period, PWM\_TMx.

When the timer register value is odd, for example 11, then that timer loads +5 at the beginning of the period, counts down from +5 to -5 in the first half, reloads -5 at the midpoint and counts up from -5 to +5 in the second half. The reload values at the period and mid-period boundaries are the same as the previous count. It totally counts  $2 \times 11 = 22$  counts in the entire period. This is shown in the figure below. Note that both half-periods have a count of 11 each.

**Figure 18-2:** Operation of Timer for Odd Value of PWM\_TM

When the timer register value is even, for example 12, then that timer loads +5 at the beginning of the period, counts from +5 to -6 in the first half, reloads -5 at the midpoint and counts up from -5 to +6 in the second half. The reload values at the period and mid-period boundaries are different from the previous count. It totally counts  $2 \times 12 = 24$  counts in the entire period. This is shown in the figure below. Note that both half-periods have a count of 12 each.

**Figure 18-3:** Operation of Timer for Even Value of PWM\_TM

Note that in the operation discussed in this section, double buffering of all channel registers and the timer registers take place at the period boundary of the respective timers.

## Phase Offset Control

The PWM timers (PWMTMR1 through PWMTMR4) can operate with a programmable phase lag with respect to the main timer, PWMTMR0. Using DLY x delay counter in conjunction with PWMTMR0 and setting the  $PWM\_CTL.DLYAEN$  bit implements this feature for a given channel.

If this feature is enabled for channel A (and channel A is using PWMTMR1 for generating duty cycle), when PWMTMR0 reaches its period boundary, it triggers, DLY A, which counts out SCLK cycles equal in number to the value programmed in the  $PWM\_DLYA$  register. At the end of this count, DLY x sends out a trigger to PWMTMR1. Thus PWMTMR1 receives a synchronization pulse in every period of PWMTMR0 at a point delayed from its period boundary by the value in  $PWM\_DLYA$  register. For more information on how channels can reference different timers for their outputs, see "Channel Timing Control Unit"

**NOTE:** The following conditions must be satisfied when this feature is used on PWMTMRy for channel Y with respect to PWMTMRx.

- The  $PWM\_DLYA$  register must be programmed to a value less than  $2 \times TMy$
- $PWM\_TM0 = N \times PWM\_TMy$  where N is an integer.

The function of PWMTMR<sub>y</sub> (PWMTMR1 in the example above) differs in cases where  $PWM\_TM0 = PWM\_TM1$  from cases where  $PWM\_TM0 = N \times PWM\_TM1$ . Both cases are examined below.

#### **Case 1: $PWM\_TM0 = PWM\_TM_y$**

In this case every period of PWMTMR<sub>y</sub> starts its period again, on reception of the synchronization pulse from DLY-x. If the trigger from DLY-x is late, it holds its count till the trigger comes. If the trigger is a bit early, it reloads without regard to whether it has completed its current period. Thus PWMTMR<sub>y</sub> is re-synched with PWMTMR0 with a phase lag as programmed in PWM\_DLYA register, in every one of its periods.

Note that in this case the expiration of the DLY x counter is the period boundary of PWMTMR<sub>y</sub>. Therefore, this is the point of update of all the double buffered registers related to the given channel (except the delay registers which are double buffered at the period boundary of PWMTMR0).

*Phase Offset Control Using DELAY* shows an example where:

- PWM\_TM0, PWM\_TM1 and PWM\_TM2 are programmed with the same value.
- PWM\_DLYA and PWM\_DLYB are programmed values DELAY1 and DELAY2 respectively, such that  $DELAY2 > DELAY1$ .
- Channel A's outputs are referenced to TMR1 and Channel B's outputs to PWMTMR2.

The delay registers are double buffered and the new value of delay is reloaded at the period boundary of PWMTMR0. The two options described below exist if the new value is different from the older one. The behavior of PWMTMR<sub>y</sub> in both these cases is discussed, in conjunction with *Impact of New DELAY Value on Timer Count for Equal TM*. It is assumed that channel B references its outputs to PWMTMR0 and channel A references its outputs to PWMTMR1.

1. The new delay value is higher than the previous value. Therefore, the corresponding PWMTMR<sub>y</sub> is allowed more than one period's time between consecutive triggers from the DLY-x counter. In this case, after reaching its period boundary, PWMTMR<sub>y</sub> holds its count at the period boundary and waits for the trigger from DLY-x. This is shown in CASE A in *Impact of New DELAY Value on Timer Count for Equal TM*.
2. The next delay value programmed is smaller than the previous value. In this case, the corresponding PWMTMR<sub>y</sub> is allowed only less than one period's time between consecutive triggers from the DLY-x counter. Though the trigger comes earlier in this case, before PWMTMR<sub>y</sub> has counted out one full period, it reloads and starts its period again. This is shown in CASE B in *Impact of New DELAY Value on Timer Count for Equal TM*.

Therefore, PWMTMR1 waits and obeys a synchronization pulse from DLY A in every one of its periods.

**Figure 18-4:** Phase Offset Control Using DELAY

**Figure 18-5:** Impact of New DELAY Value on Timer Count for Equal TM

### Case 2: $PWM\_TM0 = N \times PWM\_TM_y$

In this case, within a single period of PWM\_TMR0 a program can fit multiple periods (N) of PWM\_TMRy. Additionally, the DLY-x counter is triggered only once every N periods of PWM\_TMRy.

The operation is as follows: Every Nth period of PWM\_TMRy, it expects a synchronization pulse from DLY-x counter. When it counts out that period if the trigger hasn't yet arrived yet, it waits at the end of the period for the trigger, and starts counting down once it arrives. If the trigger comes earlier than that, it restarts immediately without waiting to complete its period count.

In the intervening periods, PWM\_TMRy operates independently. As the period ends, it reloads and starts the next period without intervention from the delay counter.

*Impact of DELAY Value Change for the Multiple TM* gives an example with  $N = 2$ . Note that PWM\_TMRy syncs up with PWM\_TMR0 every 2nd period, and is free running across every odd period boundary.

**Figure 18-6:** Impact of DELAY Value Change for the Multiple TM

## Channel Timing Control Unit

The channel timing control unit is the core of the PWM. There are four separate channels, each channel controlling a pair of output signals – the high side output and the low side output.

## Channel Control

The `PWM_CHANCFG` register controls the static configuration of all the channels and is to be initialized once before the beginning of the operation.

**NOTE:** The `PWM_CHANCFG` register is not double buffered and the contents of it must not be changed once the PWM is enabled.

Each channel works off a reference timer base. The time base can be either the main timer `PWMTMR0` or the appropriate `PWMTMRx` as given below. This can be configured with the `PWM_CHANCFG.REFTMRA` bit field.

- Channel A can work off `PWMTMR0` or `PWMTMR1`
- Channel B can work off `PWMTMR0` or `PWMTMR2`
- Channel C can work off `PWMTMR0` or `PWMTMR3`
- Channel D can work off `PWMTMR0` or `PWMTMR4`

The `PWM_xCTL` registers contain bits which control the dynamic pulse behavior of the channel outputs and this register is double buffered. This register has bits which control enable/disable and pulse positioning of the outputs. The impact of these is explained in the following sections.

## Pulse Positioning and Duty Cycle Registers

The `PWM_ACTL.PULSEMODEHI[1:0]` and `PWM_ACTL.PULSEMODELO[1:0]` fields define the region within the timer period where the output pulses should be positioned. When the `PWM_CHANCFG.MODELSC` bit is 0, the `PWM_ACTL.PULSEMODEHI` field specifies the pulse positioning for both the high-side and low-side outputs of the channel. When the bit is 1, `PWM_ACTL.PULSEMODELO` defines the pulse positioning for the low side channel output, while `PWM_ACTL.PULSEMODEHI` continues to do serve this purpose for the high side channel output.

Two Duty-Cycle registers are provided for each channel output: `PWM_AH0` and `PWM_AH1` for the high side output, and `PWM_AL0` and `PWM_AL1` for the low side output. These registers determine the width of the output pulses. When the `PWM_CHANCFG.MODELSC` bit is 0, the high side Duty-Cycle registers are used for the low side output pulse width determination as well. The duty cycle range that can be programmed into these registers is between  $-PWM_{TMx}/2$  and  $+PWM_{TMx}/2$  when dead-time is not considered.

When dead-time is considered, for `PULSEMODE 00` and `01`, the programmed duty is modified for use by the PWM in such a way that the range is limited between the values  $[-PWM_{TMx}/2 + PWM_{DT}]$  to  $[+PWM_{TMx}/2 + PWM_{DT}]$  considering the high-side output. Dead-time is explained in detail in a later section. For `PULSEMODEs 10` and `11`, the high-side Duty-Cycle registers are limited between  $[PWM_{TMx}/2 + PWM_{DT}]$  and  $[-PWM_{TMx}/2 - PWM_{DT}]$ .

**NOTE:** Values programmed into these registers that fall outside these limits result in over/under modulation.

## Duty Cycle and Pulse Positioning Control

The `PWM_ACTL.PULSEMODEHI` and `PWM_ACTL.PULSEMODELO` fields control how the Duty cycle registers modify the waveform of the high and low side outputs. (The `PWM_ACTL.PULSEMODEHI` and `PWM_ACTL.PULSEMODELO` fields are referred to as *PULSEMODE* in the subsequent discussion.)

- `PULSEMODE = 00` – Allows symmetrical pulse waveform around the center of the PWM period. In this mode, only one of the Duty Cycle registers is used for an output—for example, for the AH output, only the `PWM_AH0` register is used. Note that in this mode, the values in the duty cycle registers are scaled such that a value of 0 produces 50% duty.
- `PULSEMODE = 01` – Allows asymmetrical pulse waveform around the center of the PWM period. In this mode both the Duty Cycle registers are used. For example for the AH output, `PWM_AH0` and `PWM_AH1` registers are used. In this mode, if `PWM_AH1` is programmed with the same value as `PWM_AH0`, the obtained output is identical to that in the `PULSEMODE = 00` case.
- `PULSEMODE = 10` or `11` – Allow pulse waveforms to be produced either on the first half or the second half of the PWM period respectively, and both `PWM_AH0` and `PWM_AH1` registers are used.

**NOTE:** In `PULSEMODE = 10` the condition `PWM_AH0 > PWM_AH1`. If the low side is working off the low side Duty-Cycle registers, the condition `PWM_AL0 > PWM_AL1` should be strictly adhered to.

**NOTE:** In `PULSEMODE = 11` the condition `PWM_AH0 < PWM_AH1`. If the low side is working off the low side Duty-Cycle registers, the condition `PWM_AL0 < PWM_AL1` should be strictly adhered to.

The following figure shows the pulse positioning modes as described above for PWM\_AH. In the figure, DUTY0 is assumed to be the value in PWM\_AL0 register and DUTY1, the value in PWM\_AH1 register. The step signal, count, indicates the output of the timer that Channel A is working off. Also, in the example, the signal is assumed to be configured as active high, and dead-time is assumed to be zero.

**Figure 18-7:** Pulse Positioning Modes

## Channel Low Side Output Dependent Operation Mode and Dead-Time

The low-side output waveform can be programmed to be dependent on the high side output waveform or be totally independent. This is controlled using the PWM\_CHANCFG.MODELSC bit.

For example, the channel A produces the high side output PWM\_AH and the low side output PWM\_AL. When PWM\_CHANCFG.MODELSC = 0, the low-side output is also generated using the high-side duty-cycle registers for pulse width, PWM\_ACTL.PULSEMODEHI bits for pulse positioning and the PWM\_CHANCFG.POLAH bit for polarity. If PWM\_DT is programmed to 0, the low-side output is an inverted version of the high-side output.

When PWM\_DT is programmed with a non-zero value, both the high-side and low-side outputs are shrunk symmetrically about the points of transition in the zero dead-time case by an amount PWM\_DT.

The high and low-side outputs for the case with zero and non-zero dead-time for PWM\_ACTL.PULSEMODEHI = 00 and 01 are shown in the following figure. In the figure, DUTY0 is the value programmed into the

PWM\_AH0 register and DUTY1 is the value programmed into the PWM\_AH1 register. PWM\_CHANCFG.POLAH is 1 indicating that both signals are active high. PWM\_DT holds the value DT.

**Figure 18-8:** Channel Outputs in Dependent Mode for PULSEMODE = 00, 01

The high and low-side outputs for the case with zero and non-zero dead-time for PWM\_ACTL.PULSEMODEHI = 10 and 11 are shown in the following figure. In the figure, DUTY0 is the value programmed into PWM\_AH0 register and DUTY1 is the value programmed into the PWM\_AH1 register. PWM\_CHANCFG.POLAH is 1 indicating that both signals are active high. PWM\_DT holds the value DT.

**NOTE:** Bringing dead-time into the picture, the guidelines for programming the Duty-Cycle registers in PULSEMODEs 10 and 11 given in “PWM Duty Cycle and Pulse Positioning Control” are modified as follows:

PULSEMODE 10:  $\text{PWM\_xH0} - \text{DT} > \text{PWM\_xH1} + \text{DT}$

PULSEMODE 11:  $\text{PWM\_xH0} + \text{DT} < \text{PWM\_xH1} - \text{DT}$

**Figure 18-9:** Channel Outputs in Dependent Mode for PULSEMODE = 10, 11

## Channel High Side and Low Side Outputs, Independent Operation Mode

Independent control of the channel outputs, PWM\_AH0 and PWM\_AL0 is possible by setting the PWM\_CHANCFG.MODELSA bit to 1. In this case, PWM\_AH is generated using PWM\_AH0, PWM\_AH1 for pulse width, PWM\_ACTL.PULSEMODEHI for pulse position, and PWM\_CHANCFG.POLAH for polarity. PWM\_AL is generated using PWM\_AL0, PWM\_AL1 for pulse width, PWM\_ACTL.PULSEMODELO for pulse position and PWM\_CHANCFG.POLAL for polarity.

**NOTE:** In the independent mode, the dead-time insertion is not applicable and the dead-time is forced to zero by the hardware.

The following figure shows an example of the independent mode of operation where PWM\_AH and PWM\_AL work off different register bits.

**Figure 18-10:** PWM\_AH and PWM\_AL in Independent Operation Mode

Note that PWM\_AH and PWM\_AL can be positioned in the timer period with a given phase difference between them. This is achieved by having PULSEMODEHI and PULSEMODELO bits programmed to different values. This is shown in the next figure.

**Figure 18-11:** Channel Outputs Controlled Independently

## Switched Reluctance Motors Application

In the typical power converter configuration for switched or variable reluctance motors, the motor winding is connected between the two power switches of a given inverter leg. Therefore, to allow for a complete circuit in the motor winding, it is necessary to turn on both switches at the same time.

Switched reluctance motors are used in the following configurations: Hard Chop, Alternate Chop, Soft Chop—Bottom On, and Soft Chop—Top On.

The following figure shows the four SR mode types as active high PWM output signals.

Hard Chop mode contains independently programmed rising edges of a channel's high and low signals in the same PWM half cycle and both contain independently programmed falling edges in the next PWM half cycle. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` are programmed to same values.

Alternate Chop mode is similar to normal PWM operation but the PWM channel high and low signal edges are always opposite and are independently programmed. The `PWM_CHANCFG.POLAH` and `PWM_CHANCFG.POLAL` are programmed to opposite values. The Low Side Invert is the only difference between Hard Chop mode and Alternate Chop mode.

Soft Chop—Bottom On uses a 100% duty on the low side of the channel and Soft Chop—Top On uses a 100% duty on the high side of the channel. Similar to Hard Chop mode the `PWM_AH0` duty register is used for the high channel and `PWM_AL0` duty register is used for the low channel.

**Figure 18-12:** Four SR Mode Types, Active High PWM Output Signals

## Switching Dead Time (PWM\_DT) Register

The second important parameter that must be set up in the initial configuration of the PWM Controller is the switching dead time. This is a short delay introduced between turning off one PWM signal (for example, AH) and turning on the complementary signal (for example, AL). This short time delay permits the power switch being turned off (AH in this case) to completely recover its blocking capability before the complementary switch is turned on. This time delay prevents a potentially destructive short-circuit condition from developing across the dc link capacitor of a typical voltage source inverter.

The 10-bit, read/write PWM\_DT register controls the dead time. This register controls the dead time inserted into the three pairs of PWM output signals. Dead time ( $T_d$ ) is related to the value in the PWM\_DT register by:

$$T_d = \text{PWM\_DT} \times 2 \times t_{\text{SCLK}}$$

Therefore, a PWM\_DT value of 0x00A introduces a 200 ns delay (for a SCLK of 100 MHz) between turning off any PWM signal (for example, AH) and then turning on its complementary signal (for example, AL). The length of the dead time can therefore be programmed in increments of  $2 \times t_{\text{SCLK}}$  (or 20 ns for an SCLK of 100 MHz). The PWM\_DT register is a 10-bit register whose maximum value of 0x3FF (1023 decimal) corresponds to a maximum programmed dead time of:

$$T_{d(\text{max})} = 1023 \times 2 \times t_{\text{SCLK}} = 1023 \times 2 \times 10 \times 10^{-9} = 20.5 \mu\text{s}$$

for an  $f_{\text{SCLK}}$  rate of 100 MHz. The dead time can be programmed to be zero by writing 0 to the PWM\_DT register.

## Duty Cycle with Dead-Time Control: Calculations for PULSEMODE 00

The duty cycle registers are scaled such that a value of 0 represents a 50% PWM duty, cycle. The switching signals produced are also adjusted to incorporate the programmed dead time value in the PWM\_DT register. The unit in this case produces active low signals so that a low level corresponds to a command to turn on the associated power device.

A typical pair of PWM outputs, PWM\_AH and PWM\_AL, is shown in the following figure. The time values in the figure indicate the integer value in the associated register and can be converted to time by multiplying by the fundamental time increment,  $t_{\text{CK}}$ . In the example channel A is working off of PWMTMR0.

Because PULSEMODE is set to 00, the switching patterns are perfectly symmetrical about the mid-point of the switching period. The dead time is incorporated by moving the switching instants of both PWM signals away from the instant set by the PWM\_AH0 register. Both switching edges are moved by an equal amount ( $\text{PWMDT} \times t_{\text{CK}}$ ) to preserve the symmetrical output patterns. Also shown is the PWM\_SYNC\_OUT pulse whose rising edge denotes the beginning of the switching period, and the PWM\_STAT.TMR0PHASE bit.

**Figure 18-13:** Dead-Time Between Outputs in Dependent Mode

The resulting on-times (active low) of the PWM signals over the full PWM period (two half-periods) produced by the PWM timing unit and illustrated in the figure above, may be written as shown in the following equation.

$$T_{AH} = (PWM\_TM0 + 2 \times (PWM\_AH0 - PWM\_DT)) \times t_{CK};$$

$$\text{Range of } T_{AH} \text{ is } [0:2 \times PWM\_TM0 \times t_{CK}]$$

$$T_{AL} = (PWM\_TM0 - 2 \times (PWM\_AH0 + PWM\_DT)) \times t_{CK};$$

$$\text{Range of } T_{AL} \text{ is } [0:2 \times PWM\_TM0 \times t_{CK}]$$

The corresponding duty cycles are shown in the following equations.

$$d_{AH} = \frac{T_{AH}}{T_s} = \frac{1}{2} + \frac{PWM\_AH0 - PWM\_DT}{PWM\_TM}$$

$$d_{AL} = \frac{T_{AL}}{T_s} = \frac{1}{2} - \frac{PWM\_AH0 + PWM\_DT}{PWM\_TM0}$$

The negative values of  $T_{AH}$  and  $T_{AL}$  are not permitted and the minimum permissible value is zero, corresponding to a 0% duty cycle. In a similar fashion, the maximum value is  $T_s$ , the PWM switching period, corresponding to a 100% duty cycle. Calculation of duty for other PULSEMODOs can be similarly carried out.

## Special Consideration for PWM Operation in Over-Modulation

The PWM Timing Unit is capable of producing PWM signals with variable duty cycle values at the PWM output pins. In PULSEMODEs 00 and 01, at the extremities of the modulation process, we have 0% and 100%. IN PULSEMODEs 01 and 10, at the extremities the modulation process, we have 0% and 50%. The modulation is called FULL OFF when the lower extremity of modulation is set for any PWM timer period for the corresponding channel. The modulation is called FULL ON when the higher extremity of modulation is set for any PWM timer period for the corresponding channel. In between, for other duty cycle values, the operation is termed NORMAL MODULATION.

- Full On Modulation. In PULSEMODEs 00 and 01, a PWM channel is said to be in FULL ON modulation if the high-side output of that channel is asserted for the whole duration of the period of the PWM timer that channel is referencing. Condition for FULL ON MODULATION:  $PWM\_xH0 - DT > PWM\_TMy/2$  for PULSEMODE 00 and the additional condition that  $PWM\_xH1 - DT > PWM\_TMy/2$  as well.

In PULSEMODE 10, a PWM channel is said to be in FULL ON modulation if the high-side output of that channel is asserted for the whole duration of the first half period of the PWM timer that the channel is referencing. Condition for FULL ON MODULATION:  $PWM\_xH0 - DT > PWM\_TMy/2$  and  $PWM\_xH1 + DT < -PWM\_TMy/2$ .

In PULSEMODE 11, a PWM channel is said to be in FULL ON modulation if the high-side output of that channel is asserted for the whole duration of the second half period of the PWM timer that the channel is referencing. Condition for FULL ON MODULATION:  $PWM\_xH0 + DT < -PWM\_TMy/2$  and  $PWM\_xH1 - DT > PWM\_TMy/2$ .

- Full Off Modulation. In PULSEMODEs 00 and 01, a PWM channel is said to be in FULL OFF modulation if the high-side output of that channel is de-asserted for the whole duration of the period of the PWM timer that channel is referencing. Condition for FULL OFF MODULATION:  $PWM\_xH0 - DT < -PWM\_TMy/2$  for PULSEMODE 00 and the additional condition that  $PWM\_xH1 - DT < -PWM\_TMy/2$  as well.

In PULSEMODE 10, a PWM channel is said to be in FULL OFF modulation if the high-side output of that channel is de-asserted for the whole duration of the first half period of the PWM timer that the channel is referencing (In the second half-period it is anyway de-asserted). Condition for FULL OFF MODULATION:  $PWM\_xH0 - DT < -PWM\_TMy/2$  and  $PWM\_xH1 + DT < PWM\_xH0 - DT$ .

In PULSEMODE 11, a PWM channel is said to be in FULL OFF modulation if the high-side output of that channel is de-asserted for the whole duration of the second half period of the PWM timer that the channel is referencing (In the first half of the period it is anyway de-asserted). Condition for FULL OFF MODULATION:  $PWM\_xH0 + DT > PWM\_TMy/2$  and  $PWM\_xH1 - DT > PWM\_xH0 + DT$ .

- Normal Modulation. All other cases of modulation fall under this category.

There are certain situations, on transition either into or out of either FULL ON or FULL OFF modulation, where it is necessary to insert additional emergency dead time delays to prevent potential shoot through conditions in the inverter. Disable/Enable usage (related to DISHI and DISLO bits in PWM\_CTL register) also can potentially cause outputs to violate shoot through condition criteria. Another case is when the

phase delay of a PWM timer is varied by large values. These transitions are detected automatically and if appropriate for safety, an emergency dead-time is inserted to prevent shoot through conditions.

The insertion of the additional emergency dead time into one of the PWM signals of a given pair during these transitions is only needed if otherwise both PWM signals would be required not to toggle within a dead time of each other. The additional emergency dead time delay is inserted into the PWM signal that is toggling into the ON state. In effect the turn ON of this signal is delayed by an amount ( $2 \times \text{PWMDT} \times t_{\text{CK}}$ ) from the rising edge of the opposite output. After this delay, the PWM signal is allowed to turn ON provided the desired output is still scheduled to be in the ON state after the emergency dead time delay.

The following figure illustrates two example of such a transition. Here POLHI is kept at 1. PWM\_AH has been in FULL ON modulation for sometime, and during the current period, its PULSEMODE is changed to 10 keeping the FULL ON condition. At the half-period boundary it is forced to transition to a de-asserted state due to this being PULSEMODE 10. It can be seen that an emergency dead-time is inserted on the low-side output.

Figure 18-14: Over Modulation Transition Scenarios

## Output Disable and Cross-Over Functions

Each PWM\_ACTL channel control register contains separate enable bits for the high and low side signals. For example, the PWM\_ACTL.DISHI and PWM\_ACTL.DISLO bits in the channel A control register control the enable/disable of the AH and AL outputs respectively. If the disable bit is set ( $= 1$ ), then the corresponding PWM output is disabled, irrespective of the value of the corresponding duty cycle register. This PWM output signal remains in the OFF state as long as the corresponding enable/disable bit is set.

The PWM\_ACTL.XOVR bit, or the cross-over bit allows programs to send the low-side output through the high-side output pin and the high-side output through the low side output pin.

For example, PWM\_AH0 is programmed to zero with PWM\_CHANCFG.MODELSA = 0. With PWM\_ACTL.DISLO = 1 and PWM\_ACTL.XOVR = 1 the low-side is being toggled even though the output is disabled, but nothing is toggling on the high-side pins. What is happening is that the high-side output is now coming out through the low-side (and vice versa). What is toggling on the low-side pin is the 50% duty high side output pulse (less the dead-time if any).

The following figure shows this example. In case 1 PWM\_ACTL.XOVR = 0 and in case 2 PWM\_ACTL.XOVR = 1.

**Figure 18-15:** XOVR and DISHI/DISLO Functionality

## Brushless DC Motor (Electronically Commutated Motor) Control

In the control of an electronically commutated motor (ECM), only two inverter legs are switched at any time. Often, the high-side device in one leg must be switched on at the same time as the low-side driver in a second leg. Therefore, by programming identical duty cycles values for two PWM channels (for example,  $PWM\_CHA = PWM\_CHB$ ) and setting the  $PWM\_BCTL.XOVR$  bit to crossover the BH/BL pair if PWM signals, it is possible to turn on the high-side switch of phase A and the low-side switch of phase B at the same time.

To control ECM, normally the third inverter leg (phase C in this example) is disabled for a number of PWM cycles. To implement this function, both the  $PWM\_CH$  and  $PWM\_CL$  outputs are disabled by setting the  $PWM\_CTL.DISHI$  and  $PWM\_CTL.DISLO$  bits.

In normal ECM operation, each inverter leg is disabled for certain time periods so that the PWM channel registers change based on the position of the rotor shaft (motor commutation).

**Figure 18-16:** ECM Control

For the situation illustrated in the figure, an appropriate value for the `PWM_SEG` register is 0x00A7. In normal ECM operation, each inverter leg is disabled for certain lengths of time, such that the `PWM_SEG` register is changed, based upon the position of the rotor shaft (motor commutation).

## Gate Drive Unit

The Gate Drive Unit of the PWM adds features that simplify the design of isolated gate drive circuits for PWM inverters. If a transformer coupled power device gate drive amplifier is used then the active PWM signal must be chopped at a high frequency. The `PWM_CHOPCFG` register allows the programming of this high frequency chopping mode. The chopped active PWM signals may be required for the high-side drivers only, for the low-side drivers only or for both the high-side and low-side switches. Therefore, independent control of this mode for both high and low-side switches is included with two separate control bits in the `PWM_CHANCFG` register.

Typical PWM output signals with high-frequency chopping enabled on both high-side and low-side signals are shown in the figure below. Chopping of the PWM outputs is enabled by setting bits in `PWM_CHANCFG` register. The high frequency chopping frequency is controlled by the 8-bit `PWM_CHOPCFG.VALUE` value in the `PWM_CHOPCFG` register. The period of this high frequency carrier is then given by,

$$T_{chop} = [4 \times (CHOPDIV + 1)] \times t_{CK}$$

and the chopping frequency is therefore an integral subdivision of the peripheral clock frequency:

$$f_{\text{chop}} = f_{\text{CK}} / [4 \times (\text{CHOPDIV} + 1)]$$

The PWM\_CHOPCFG.VALUE value may range from 0 to 255, corresponding to a programmable chopping frequency rate from 122 kHz to 31.25 MHz for a 125 MHz,  $f_{\text{CK}}$  rate. The gate drive features must be programmed before operation of the PWM controller and are not changed during normal operation of the PWM controller. Following a reset, all bits of the PWM\_CHANCFG register are cleared so that high frequency chopping is disabled, by default.

**Figure 18-17:** Hi-Side and Lo-Side Outputs With Gate Chop Enabled

## Output Control Feature Precedence

It is important to understand the order in which output control features are applied to the PWM signal. The following hierarchy indicates the order (from most important to least important) in which signal features are applied to the PWM output signal.

1. Channel duty generation
2. Channel Crossover
3. High-side/Low-side disable
4. Emergency dead time insertion
5. Gate drive chopping
6. Polarity

## Sync Operation

The PWM\_SYNC signal can be internally generated as a function of PWM\_TMO.VALUE and PWM\_SYNC\_WID.VALUE or can be input externally. Multiple PWM configurations can be established with each PWM operating with its own independent PWM\_SYNC or from its own or shared external PWM\_SYNC signal. The external PWM\_SYNC can be synchronous to the internal clock as in the case of a primary PWM

generating an internal PWM\_SYNC signal which drives the secondary PWM\_SYNC\_IN pin. The external PWM\_SYNC can also be asynchronous to the internal clock as is typically the case of an off-chip PWM\_SYNC signal used to drive each PWM's PWM\_SYNC\_IN pin.

## Internal PWM SYNC Generation

The PWM controller produces an output PWM synchronization pulse at a rate equal to period of a selected PWM timer. Programming the PWM\_CTL.INTSYNCREF field controls this selection.

Further, if the other timers are running with a non-zero DELAY offset in relation to PWMTMR0 and the PWM\_SYNC pulse is referenced to any of these timers, then the PWM\_SYNC pulses are generated at their respective period boundaries which has the lag-lead offset compared to PWMTMR0.

This pulse is available for external use at the PWM\_SYNC\_OUT pin. The width of the PWM\_SYNC pulse is programmable by the 10-bit read/write PWM\_SYNC\_WID register. The width of the PWM\_SYNC pulse,  $t_{PWM\_SYNC}$ , is given by the following equation.

$$t_{PWM\_SYNC} = t_{CLK} \times (PWMSYNCWT + 1)$$

The width of the pulse is programmable from  $t_{CLK}$  to  $1024t_{CLK}$  (corresponding to 8 ns to 8.19  $\mu$ s for a  $f_{CLK}$  rate of 125 MHz). Following a reset, the PWM\_SYNC\_WID register contains 0x3FF (1023 decimal) so that the default PWM\_SYNC width is 8.19  $\mu$ s, for a 125 MHz  $f_{CLK}$ .

## External PWM SYNC Generation

By setting the PWM\_CTL.EXTSYNC bit, the PWM is set up in a mode to expect an external PWM\_SYNC on the PWM\_SYNC\_IN pin. The external PWM\_SYNC only determines the operation of the main timer PWMTMR0.

The external sync should be synchronized by setting the PWM\_CTL.EXTSYNCSEL bit to 0 (assumes the external PWM\_SYNC selected is asynchronous).

The external PWM\_SYNC period is expected to be an integer multiple of the value of the PWM\_TMO period register. When the rising edge of the external PWM\_SYNC is detected, the PWMTMR0 timer is restarted at the beginning of its period. If the external PWM\_SYNC period is not exactly an integer multiple of the internal PWM\_SYNC, the behavior of the PWM channel outputs which are referenced to PWMTMR0 are clipped.

The effect latency from PWM\_SYNC\_IN to the PWM outputs is about three clock cycles in synchronous mode, and five clock cycles in asynchronous mode.

## Event Control

The PWM output signals can be shut-off in a number of different ways. Two trip inputs pwm\_trip0b, and pwm\_trip1b are provided, each of which can be mapped to provide either a temporary or permanent shut-down on any pair of channel outputs. This shutdown mechanism is asynchronous so that the associated PWM output disable circuitry does not go through any clocked logic, ensuring correct PWM shutdown

even in the event of a loss of the processor clock. In addition to the hardware shutdown features, the PWM system may be shutdown in software by means of the `PWM_CTL.SWTRIP` bit.

Status information about the PWM is available to the user in the `PWM_STAT` register, which stores all status bits, including raw interrupt status bits. In particular, the period boundary of each timer is available, as well as status bits that indicate whether the operation is in the first half or the second half of the timer. Additionally the TRIP status is also available.

The `PWM_IMSK` and `PWM_ILAT` registers allow masking and show masked interrupt status bits respectively. The interrupt bits are latched and held on the interrupt event and the software must write a 1 to clear the interrupt bit, usually during the Interrupt Service routine.

## Trip Control Unit

The PWM Trip unit processes hardware or software fault conditions and shuts down the PWM channel outputs immediately on the occurrence of these conditions. This shut down mechanism can be enabled separately for each channel. The design also allows for a self-restart mechanism to be enabled on a channel. Self-restart re-enables the channel outputs following the fault condition (allowed only on hardware trips) when the PWMTMR-y that the channel is using reaches its period boundary.

There are 2 external hardware sources that can indicate a hardware fault condition:

1. `PWMTRIP0` input pin
2. `PWMTRIP1` input pin

These are active low inputs where a falling edge on either of these pins indicates a fault condition.

To enable the trip unit to shut down a particular channel's output in response to the fault event on either of these `PWM_TRIPN` pins, program the `PWM_TRIPCFG.ENOA` bit corresponding to that channel.

The `PWM_TRIPCFG.MODE0A` bits must be programmed to specify the restart mechanism for a channel that has been tripped.

1. If `PWM_TRIPCFG.MODE0A = 0`, once tripped, a trip condition is registered on this channel in the `PWM_STAT.FLTTRIPA` bit and the outputs of that channel are immediately shut down. This is called a **FAULT TRIP** condition. To resume channel output when a FAULT TRIP occurs, clear the `PWM_STAT.FLTTRIPA` bit by writing a 1 to it. Note that the bit cannot be cleared by a processor write if the trip condition is still active. The RAW trip status is available for both the pins in the `PWM_STAT.RAWTRIP0` register bits.
2. If `PWM_TRIPCFG.MODE0A = 1`, once tripped, a trip condition is registered on this channel in the `PWM_STAT.SRTRIPA` bit and the outputs of that channel are immediately shut down. This is called a **self-restart trip** condition. At the next period boundary of the PWMTMR-y that the channel is using, if the tripping condition is not active, the design clears the status register bit and restores the outputs.

The trip input pins should have an external pull-down resistor on the chip pin, so that if the pin becomes unconnected the PWM will be disabled.

In addition to the hardware trip conditions, a global software trip bit in the `PWM_CTL` register allows for a software forced FAULT TRIP condition. When the global software trip bit is set to 1, irrespective of the values in the `PWM_TRIPCFG` register, it sets all the `PWM_STAT.FLTTRIPA` bits in the `PWM_STAT` register and also gates the channel outputs. To remove the trip condition from the channel, a W1C should be performed on the particular channel's `PWM_STAT.FLTTRIPA` bit.

If the `PWM_TRIPCFG.ENOA` bit is set to 1 to, for any channel, then the occurrence of a fault condition on the `PWMTRIPy` bit is logged in the `PWM_STAT.FLTTRIPA` register bit. If the corresponding `PWM_IMSK.TRIPO` bit = 1, then an interrupt is generated. Note that tripping a channel output doesn't interfere with `PWM_SYNC` generation.

The following figure shows a scenario where `PWMTRIP0` is enabled on channel A as SELF RESTART TRIP. Channel A works with `PWM_CHANCFG.POLAH = 1`. Note that in Period 2, `PWM_AH` is full ON modulated, and tries to rise at the period boundary itself where the self-restart occurs for the channel. However, since the low-side output of the channel was only recently removed due to a trip, the rise edge on `PWM_AH` is delayed until the emergency dead-time period is over. `PWMTRIP1` is enabled on channel B as FAULT TRIP. Channel B works with `PWM_CHANCFG.POLAH = 0`. `PWMTRIP1` stays low for a long time, and because of this the first processor write to re-enable the channel output fails. The second one passes since the fault-condition has gone away.

**Figure 18-18:** Operation Under Hardware Fault Conditions

**NOTE:**

Dead-time is ensured on re-enabling the channel outputs after trip.

**NOTE:**

Programs should not allow changes in the configuration/enable bits of PWM\_TRIPCFG register (which select between trip enable and disable) within  $\pm 10$  clock cycles of the toggling of external trip pulse. If this time frame is not followed, then unexpected behavior occurs.

## Programming Model

The following sections provide general (and some application specific) programming steps for configuring and using the PWM module.

- [Programming Model for 3-Phase AC Motor Control](#)

## Programming Model for 3-Phase AC Motor Control

The [PWM Module and Interaction with System](#) figure shows how the PWM unit (green) interfaces to both software (blue) and hardware (yellow). The software configures the unit, calculates duty cycles (Duty A, Duty B, Duty C), and services the interrupts generated by the module (PWM Sync IRQ, TRIP IRQ). The hardware applies the gate signals (AH, AL, BH, BL, CH, CL) to the inverter and provides an overcurrent trip signal back to the unit (TRIP0).

The typical 3-phase AC motor configuration shown in the [PWM Module and Interaction with System](#) figure applies for both permanent magnet and induction motor types.

**Figure 18-19:** PWM Module and Interaction with System

## System Parameters

The following system parameters (characteristics) influence the module configuration for this application. This example system has/uses:

- One 3-phase AC machine
- B6 inverter
- SVPWM, including both linear- and over-modulation
- Switching frequency of 20 kHz
- Dead time of 1us
- Trip signal generated by hardware
- Active high level gate drive
- Core frequency of 200 MHz
- Peripheral clock of 100 MHz

## System State Sequencing

Managing the system state and sequence of states is critically important when programming the PWM module. The *PWM System States* figure provides an overview of these states.

**Figure 18-20:** PWM System States

As shown in this state diagram, the module configuration is updated on state transitions (indicated by the arrows). The transitions are initialization, motor start, PWM sync interrupt (on each), and motor stop. These transitions are discussed in detail in the following sections.

- *PWM Initialization for Motor Control*
- *PWM Enable for Motor Control*
- *PWM Response to Sync Interrupt for Motor Control*
- *PWM Disable (and Stop the Motor) for Motor Control*

## PWM Initialization for Motor Control

The processor should do the following programming at power up and repeat this programming whenever the PWM and system must be brought into a known (safe) state.

1. Place the PWM module in a safe state and set up synchronization of the module.

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_CTL and PWM\_CHANCFG register accomplish this PWM state:

```
PWM_CTL &= 0xFFE0FF08  
PWM_CTL |= 0x20000
```

```
PWM_CHANCFG &= 0x80808080
PWM_CHANCFG |= 0x24242424
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Disable PWM ( PWM\_CTL.GLOBEN = 0)
- All phases must run with same phase, disable delay for channels A, B, C, D (PWM\_CTL.DLYAEN through PWM\_CTL.DLYDEN =0)
- Use internal synchronization by timer TMR0 (PWM\_CTL.EXTSYNC =0, PWM\_CTL.EXTSYNCSEL =1)
- All phases must be synchronized by the same timer, TMR0 (PWM\_CTL.INTSYNCREF = b#000)
- Low side is always the inverse of High side (PWM\_CHANCFG.POLAL through PWM\_CHANCFG.POLDL = 1)
- System uses active high gate driver (PWM\_CHANCFG.ENCHOPAH through PWM\_CHANCFG.ENCHOPDH =1)
- Pulse transformer is not used: disable gate chopping (PWM\_CHANCFG.ENCHOPAL through PWM\_CHANCFG.ENCHOPDL =0)

## 2. Set up the trip and associated interrupts.

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_TRIPCFG and PWM\_ILAT register accomplish this PWM state:

```
PWM_TRIPCFG &= 0xF0F0F0F0
PWM_TRIPCFG |= 0x1010101
PWM_ILAT &= 0xFFE0FFFC
PWM_ILAT |= 0x1
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- All phases must shut down simultaneously in case of fault: (PWM\_TRIPCFG.ENOA through PWM\_TRIPCFG.ENOD =0, PWM\_TRIPCFG.MODEOA through PWM\_TRIPCFG.MODEOD =0,

PWM\_TRIPCFG.EN1A through PWM\_TRIPCFG.EN1D =0, PWM\_TRIPCFG.MODE1A through PWM\_TRIPCFG.MODE1D =0)

- Enable TRIP0 as fault trigger for all channels. (PWM\_TRIPCFG.EN0A through PWM\_TRIPCFG.MODE1D =1)
  - For thermal control and synchronization, SW intervention is needed at trip. Do not use automatic restart of any channels
  - Generate an interrupt at trip on TRIP0. (PWM\_ILAT.TMROPER = 1)
3. Configure the PWM channels.

*ADDITIONAL INFORMATION:*

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_TRIPCFG and PWM\_ILAT register accomplish this PWM state:

```
PWM_DT = 0x32
PWM_TMO = 0x9C4
PWM_ACTL &= 0xFFFFF0000
PWM_BCTL &= 0xFFFFF0000
PWM_CCTL& = 0xFFFFF0000
PWM_AH0 = 0x0
```

```
PWM_BH0 = 0x0
PWM_CH0 = 0x0
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Configure a dead time of 1  $\mu$ s (PWM\_DT = 0x32).
- Configure a PWM frequency of 20 kHz (PWM\_TMO = 0x9C4).
- Disable all outputs (PWM\_ACTL.DISHI- PWM\_CCTL.DISHI = 0, PWM\_ACTL.DISLO through PWM\_CCTL.DISLO = 0)
- Use conventional PWM, disable crossover (PWM\_ACTL.XOVR through PWM\_CCTL.XOVR = 0)
- Use symmetrical pulse position on all outputs (PWM\_ACTL.PULSEMODEHI through PWM\_CCTL.PULSEMODEHI = 0, PWM\_ACTL.PULSEMODELO through PWM\_CCTL.PULSEMODELO = 0)
- Set an initial duty-cycle of 50% (PWM\_AH0 through PWM\_CH0 = 0x0)

## PWM Enable for Motor Control

The processor must do the following programming to enable the PWM before starting the motor.

1. Start the PWM timer TMR0.

*ADDITIONAL INFORMATION:* The following bitwise operation on the PWM\_CTL register accomplishes this PWM state:

```
PWM_CTL |= 0x1
```

*ADDITIONAL INFORMATION:* This operation achieves the following bit setting:

- Enable PWM ( PWM\_CTL.GLOBEN =1)

2. Enable six PWM outputs.

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_ACTL through PWM\_CCTL registers accomplish this PWM state:

```
PWM_ACTL |= 0x3
PWM_BCTL |= 0x3
PWM_CCTL |= 0x3
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Enable high and low side channel outputs (PWM\_ACTL.DISHI through PWM\_CCTL.DISHI = 1, PWM\_ACTL.DISLO through PWM\_CCTL.DISLO = 1)

3. Enable the PWM TRIP0 interrupt.

*ADDITIONAL INFORMATION:* The following bitwise operation on the PWM\_ILAT register accomplishes this PWM state:

```
PWM_ILAT |= 0x1
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Enable PWM TRIP0 interrupt ( `PWM_ILAT.TRIPO =1`)

## **PWM Response to Sync Interrupt for Motor Control**

When the PWM sync interrupt occurs, the processor may need to update to the PWM duty cycle with a value calculated by the motor control algorithm. This application uses symmetric pulses position and uses dependent High and Low side outputs, so only one register needs to be updated for each phase.

1. Write new duty cycle value (calculated by motor control algorithm) to the timer when the sync interrupt occurs.

*ADDITIONAL INFORMATION:* The following bitwise operations on the `PWM_AH0` through `PWM_CH0` registers accomplish this PWM state:

```
PWM_AH0 = Duty_A_mc_algorithm_current_value
```

*ADDITIONAL INFORMATION:*

```
PWM_BH0 = Duty_B_mc_algorithm_current_value
```

*ADDITIONAL INFORMATION:*

```
PWM_CH0 = Duty_C_mc_algorithm_current_value
```

*ADDITIONAL INFORMATION:*

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

## PWM Disable (and Stop the Motor) for Motor Control

The processor should do the following programming to stop the motor, disable the PWM, and disable PWM interrupts. These actions place the PWM and system in a safe, passive state.

1. Disable the PWM timer.

*ADDITIONAL INFORMATION:* The following bitwise operation on the PWM\_CTL register accomplish this PWM state:

```
PWM_CTL &= 0xFFFFFFFF
```

*ADDITIONAL INFORMATION:* This operation achieves the following bit setting:

- Disable PWM (PWM\_CTL.GLOBEN = 0)

2. Disable all PWM outputs.

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_ACTL through PWM\_CCTL registers accomplish this PWM state:

```
PWM_ACTL &= 0xFFFFFFFFC
```

```
PWM_BCTL &= 0xFFFFFFFFC
```

```
PWM_CCTL &= 0xFFFFFFFFC
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Disable PWM outputs PWM\_ACTL.DISHI through PWM\_CCTL.DISHI = 1, PWM\_ACTL.DISLO through PWM\_CCTL.DISLO = 0)

3. Set the PWM duty-cycle to 50%.

*ADDITIONAL INFORMATION:* The following bitwise operations on the PWM\_AHO through PWM\_CHO registers accomplish this PWM state:

```
PWM_AHO = 0x0
```

```
PWM_BHO = 0x0
```

```
PWM_CHO = 0x0
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Set PWM duty cycle to 50%. (PWM\_AHO.DUTY through PWM\_CHO.DUTY = 0)

4. Disable the PWM TRIP0 interrupt.

*ADDITIONAL INFORMATION:* The following bitwise operation on the PWM\_ILAT register accomplish this PWM state:

```
PWM_ILAT &= 0xFFFFFFFF
```

*ADDITIONAL INFORMATION:* These operations achieve the following bit settings:

- Disable PWM TRIP0 interrupt (PWM\_ILAT.TRIPO = 0)

## PWM Register Descriptions

Pulse-Width Modulator (PWM) contains the following registers.

**Table 18-5:** PWM Module Registers

| Name         | Description                    |
|--------------|--------------------------------|
| PWM_CTL      | Control Register               |
| PWM_CHANCFG  | Channel Config Register        |
| PWM_TRIPCFG  | Trip Config Register           |
| PWM_STAT     | Status Register                |
| PWM_IMSK     | Interrupt Mask Register        |
| PWM_ILAT     | Interrupt Latch Register       |
| PWM_CHOPCFG  | Chop Configuration Register    |
| PWM_DT       | Dead Time Register             |
| PWM_SYNC_WID | Sync Pulse Width Register      |
| PWM_TM0      | Timer 0 Period Register        |
| PWM_TM1      | Timer 1 Period Register        |
| PWM_TM2      | Timer 2 Period Register        |
| PWM_TM3      | Timer 3 Period Register        |
| PWM_TM4      | Timer 4 Period Register        |
| PWM_DLYA     | Channel A Delay Register       |
| PWM_DLYB     | Channel B Delay Register       |
| PWM_DLYC     | Channel C Delay Register       |
| PWM_DLYD     | Channel D Delay Register       |
| PWM_ACTL     | Channel A Control Register     |
| PWM_AH0      | Channel A-High Duty-0 Register |

**Table 18-5:** PWM Module Registers (Continued)

| Name     | Description                          |
|----------|--------------------------------------|
| PWM_AH1  | Channel A-High Duty-1 Register       |
| PWM_AL0  | Channel A-Low Duty-0 Register        |
| PWM_AL1  | Channel A-Low Duty-1 Register        |
| PWM_BCTL | Channel B Control Register           |
| PWM_BH0  | Channel B-High Duty-0 Register       |
| PWM_BH1  | Channel B-High Duty-1 Register       |
| PWM_BL0  | Channel B-Low Duty-0 Register        |
| PWM_BL1  | Channel B-Low Duty-1 Register        |
| PWM_CCTL | Channel C Control Register           |
| PWM_CH0  | Channel C-High Pulse Duty Register 0 |
| PWM_CH1  | Channel C-High Pulse Duty Register 1 |
| PWM_CL0  | Channel C-Low Pulse Duty Register 0  |
| PWM_CL1  | Channel C-Low Duty-1 Register        |
| PWM_DCTL | Channel D Control Register           |
| PWM_DH0  | Channel D-High Duty-0 Register       |
| PWM_DH1  | Channel D-High Pulse Duty Register 1 |
| PWM_DL0  | Channel D-Low Pulse Duty Register 0  |
| PWM_DL1  | Channel D-Low Pulse Duty Register 1  |

## Control Register

The PWM\_CTL register enables the PWM, enables delay counters for the channels, and configures sync features. This register also provides support for tripping a PWM fault condition through software.

PWM\_CTL: Control Register - R/W

Reset = 0x0002 0000

Figure 18-21: PWM\_CTL Register Diagram

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                          |
|---------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20:18   | INTSYNCREF | Timer reference for Internal Sync.<br>The PWM_CTL . INTSYNCREF bits select the timer reference for the internal sync. Note that all other combinations reserved. |
|         |            | 0 PWMTMR0 provides sync reference                                                                                                                                |
|         |            | 1 PWMTMR1 provides sync reference                                                                                                                                |
|         |            | 2 PWMTMR2 provides sync reference                                                                                                                                |
|         |            | 3 PWMTMR3 provides sync reference                                                                                                                                |
|         |            | 4 PWMTMR4 provides sync reference                                                                                                                                |

**Table 18-6:** PWM\_CTL Register Fields (Continued)

| Bit No. | Bit Name    | Description/Enumeration                                                                                                                                                                                                                                                                          |
|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17      | EXTSYNCSSEL | External Sync Select.<br>The PWM_CTL.EXTSYNCSSEL bit selects whether the external sync signal is synchronous or asynchronous. Note that latency in PWM sync response differs between asynchronous and synchronous external sync modes. For more information, see the PWM functional description. |
|         |             | 0 Asynchronous External Sync                                                                                                                                                                                                                                                                     |
|         |             | 1 Synchronous External Sync                                                                                                                                                                                                                                                                      |
| 16      | EXTSYNC     | External Sync.<br>The PWM_CTL.EXTSYNC bit selects whether the PWM uses an external or internal sync signal for the main timer (PWMTMR0). Do not change the value of the PWM_CTL.EXTSYNC bit while the PWM is enabled (PWM_CTL.GLOBEN =1).                                                        |
|         |             | 0 Internal sync used                                                                                                                                                                                                                                                                             |
|         |             | 1 External sync used                                                                                                                                                                                                                                                                             |
| 7       | DLYDEN      | Enable Delay Counter for Channel D.<br>The PWM_CTL.DLYDEN bit enables the Channel D delay counter, supporting phase-offset control. Do not change the value of the PWM_CTL.DLYDEN bit while the PWM is enabled (PWM_CTL.GLOBEN =1).                                                              |
|         |             | 0 Disable                                                                                                                                                                                                                                                                                        |
|         |             | 1 Enable                                                                                                                                                                                                                                                                                         |
| 6       | DLYCEN      | Enable Delay Counter for Channel C.<br>The PWM_CTL.DLYCEN bit enables the Channel C delay counter, supporting phase-offset control. Do not change the value of the PWM_CTL.DLYCEN bit while the PWM is enabled (PWM_CTL.GLOBEN =1).                                                              |
|         |             | 0 Disable                                                                                                                                                                                                                                                                                        |
|         |             | 1 Enable                                                                                                                                                                                                                                                                                         |

**Table 18-6:** PWM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                     |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | DLYBEN   | Enable Delay Counter for Channel B.<br>The PWM_CTL.DLYBEN bit enables the Channel B delay counter, supporting phase-offset control. Do not change the value of the PWM_CTL.DLYBEN bit while the PWM is enabled (PWM_CTL.GLOBEN =1).                                         |
|         |          | 0      Disable                                                                                                                                                                                                                                                              |
|         |          | 1      Enable                                                                                                                                                                                                                                                               |
| 4       | DLYAEN   | Enable Delay Counter for Channel A.<br>The PWM_CTL.DLYAEN bit enables the Channel A delay counter, supporting phase-offset control. Do not change the value of the PWM_CTL.DLYAEN bit while the PWM is enabled (PWM_CTL.GLOBEN =1).                                         |
|         |          | 0      Disable                                                                                                                                                                                                                                                              |
|         |          | 1      Enable                                                                                                                                                                                                                                                               |
| 2       | SWTRIP   | Software Trip.<br>The PWM_CTL.SWTRIP bit permits tripping a fault condition through software, shutting down PWM output. This bit always read as 0. If the PWM_CTL.SWTRIP bit and PWM_CTL.GLOBEN bit are set in the same write, the write does not trip the fault condition. |
|         |          | 1      Force a Fault Trip Condition                                                                                                                                                                                                                                         |
| 1       | EMURUN   | Output Behavior During Emulation Mode.<br>The PWM_CTL.EMURUN bit selects PWM output behavior during emulation mode.                                                                                                                                                         |
|         |          | 0      Disable Outputs                                                                                                                                                                                                                                                      |
|         |          | 1      Enable Outputs                                                                                                                                                                                                                                                       |

**Table 18-6:** PWM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | GLOBEN   | Module Enable.<br>The PWM_CTL.GLOBEN bit enables the PWM, enabling all timers and outputs. While this bit is enabled, processor code should not change the value of the PWM_CTL.DLYAEN bit, PWM_CTL.DLYBEN bit, PWM_CTL.DLYCEN bit, PWM_CTL.DLYDEN bit, PWM_CTL.EXTSYNCSEL bit, or any bits in the PWM_CHANCFG register. Note that there is a latency between PWM disable and the cessation of output waveforms. There is also a latency between PWM enable and start of output waveforms. For the latency description, see the PWM functional description. |
|         |          | 0                      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|         |          | 1                      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Channel Config Register

The PWM\_CHANCFG register configures Channel A, B, C, and D reference timer selection, high and low side output features, and enables high frequency chopping operation. Do not change the value of any bits in the PWM register while the PWM is enabled (PWM\_CTL.GLOBEN =1).

PWM\_CHANCFG: Channel Config Register - R/W

Reset = 0x0000 0000

Figure 18-22: PWM\_CHANCFG Register Diagram

**Table 18-7:** PWM\_CHANCFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30      | ENCHOPDL | Channel D Gate Chopping Enable Low Side.<br>The PWM_CHANCFG.ENCHOPDL bit enables mixing of the Channel D low side output signals with a high-frequency chopping signal, which is configured with the PWM_CHOPCFG register.   |
|         |          | 0      Disable Chopping Channel D Low Side                                                                                                                                                                                   |
|         |          | 1      Enable Chopping Channel D Low Side                                                                                                                                                                                    |
| 29      | POLDL    | Channel D low side Polarity.<br>The PWM_CHANCFG.POLDL bit selects the Channel D low side output polarity (active-high or active-low).                                                                                        |
|         |          | 0      Active Low                                                                                                                                                                                                            |
|         |          | 1      Active High                                                                                                                                                                                                           |
| 27      | ENCHOPDH | Channel D Gate Chopping Enable High Side.<br>The PWM_CHANCFG.ENCHOPDH bit enables mixing of the Channel D high side output signals with a high-frequency chopping signal, which is configured with the PWM_CHOPCFG register. |
|         |          | 0      Disable Chopping Channel D High Side                                                                                                                                                                                  |
|         |          | 1      Enable Chopping Channel D High Side                                                                                                                                                                                   |
| 26      | POLDH    | Channel D High side Polarity.<br>The PWM_CHANCFG.POLDH bit selects the Channel D high side output polarity (active-high or active-low).                                                                                      |
|         |          | 0      Active Low                                                                                                                                                                                                            |
|         |          | 1      Active High                                                                                                                                                                                                           |

**Table 18-7:** PWM\_CHANCFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25      | MODELSD  | Channel D Mode of low Side Output.<br>The PWM_CHANCFG.MODELSD bit selects whether the low side output waveform is based on independent controls or whether the low side output depends on the high side output controls. When PWM_CHANCFG.MODELSD =0, the low side output is an inverted form of the high side output, which is generated using the PWM_BH0 and PWM_BH1 registers for pulse width, using the PWM_BCTL.PULSEMODEHI bits for pulse positioning, and PWM_CHANCFG.POLBH bits for polarity. |
|         |          | 0      Invert of high output                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1      Independent control                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 24      | REFTMRD  | Channel D Timer Reference.<br>The PWM_CHANCFG.REFTMRD bit selects whether the PWM uses PWMTMR1 or PWMTMR0 as the reference timer for Channel D operation.                                                                                                                                                                                                                                                                                                                                              |
|         |          | 0      PWMTMR0 is Channel D reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |          | 1      PWMTMR1 is Channel D reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 22      | ENCHOPCL | Channel C Gate Chopping Enable Low Side.<br>The PWM_CHANCFG.ENCHOPCL bit enables mixing of the Channel C low side output signals with a high-frequency chopping signal, which is configured with the PWM_CHOPCFG register.                                                                                                                                                                                                                                                                             |
|         |          | 0      Disable Chopping Channel C Low Side                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 3       | ENCHOPAH | Channel A Gate Chopping Enable High Side.<br>The PWM_CHANCFG.ENCHOPAH bit enables mixing of the Channel A high side output signals with a high-frequency chopping signal, which is configured with the PWM_CHOPCFG register.                                                                                                                                                                                                                                                                           |
|         |          | 0      Disable Chopping Channel A High Side                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      Enable Chopping Channel A High Side                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2       | POLAH    | Channel A High side Polarity.<br>The PWM_CHANCFG.POLAH bit selects the Channel A high side output polarity (active-high or active-low).                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 0      Active Low                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1      Active High                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1       | MODELSA  | Channel A Mode of low Side Output.<br>The PWM_CHANCFG.MODELSA bit selects whether the low side output waveform is based on independent controls or whether the low side output depends on the high side output controls. When PWM_CHANCFG.MODELSA =0, the low side output is an inverted form of the high side output, which is generated using the PWM_AH0 and PWM_AH1 registers for pulse width, using the PWM_ACTL.PULSEMODEHI bits for pulse positioning, and PWM_CHANCFG.POLAH bits for polarity. |
|         |          | 0      Invert of high output                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1      Independent control                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 0       | REFTMRA  | Channel A Timer Reference.<br>The PWM_CHANCFG.REFTMRA bit selects whether the PWM uses PWMTMR1 or PWMTMR0 as the reference timer for Channel A operation.                                                                                                                                                                                                                                                                                                                                              |
|         |          | 0      PWMTMR0 is Channel A reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |          | 1      PWMTMR1 is Channel A reference                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Trip Config Register

The PWM\_TRIPCFG register configures Channel A, B, C, and D trip operation for trip inputs TRIP0 and TRIP1.

**PWM\_TRIPCFG: Trip Config Register - R/W**

Reset = 0x0000 0000

**Figure 18-23: PWM\_TRIPCFG Register Diagram**

**Table 18-8: PWM\_TRIPCFG Register Fields**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                    |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 27      | MODE1D   | Mode of TRIP1 for Channel D.<br>The PWM_TRIPCFG.MODE1D bit selects the trip mode of TRIP1 for Channel D. For more information, see the PWM_TRIPCFG.MODE0A bit description. |
|         |          | 0 Fault Trip on TRIP1 Input                                                                                                                                                |

**Table 18-8:** PWM\_TRIPCFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                             |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| 1       | MODE0A   | <p>Mode of TRIP0 for Channel A.</p> <p>The PWM_TRIPCFG.MODE0A bit selects the trip mode of TRIP0 for Channel A.</p> <p>In fault-trip mode (PWM_TRIPCFG.MODE0A =0), after the input is tripped, the trip status appears in the corresponding channel's fault-trip status bit (for example, PWM_STAT.FLTTRIPA), and the PWM immediately shuts down outputs of that channel. After a fault trip occurs, when the trip condition is no longer active, the processor may cause channel outputs to resume by completing a write-1-to-clear the corresponding fault-trip status bit. The raw (input level) trip input state is available from the PWM_STAT.RAWTRIP0 and PWM_STAT.RAWTRIP0 bits.</p> <p>In self-restart mode (PWM_TRIPCFG.MODE0A =1), after the input is tripped, the trip status appears in the corresponding channel's self-restart status bit (for example, PWM_STAT.SRTRIPA), and the PWM immediately shuts down outputs of that channel. On the next timer period boundary (of the PWMTMRx used by that channel), if the trip condition is not active, the PWM clears the status and restarts the channel's output.</p> |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Fault Trip on TRIP0 Input   |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Self Restart on TRIP0 Input |

## Status Register

The PWM\_STAT register indicates the PWM PWMTRIP1-0 fault and input level status, indicates the Channel A-D fault and self-restart status, and indicates the PWMTMR4-0 phase.

PWM\_STAT: Status Register - R/W

Reset = 0x0000 0000

**Table 18-9:** PWM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19      | TMR3PER  | PWMTMR3 Period Boundary Status.<br>The PWM_STAT.TMR3PER bit indicates whether or not the PWMTMR3 period boundary has been reached.                                                                       |
|         |          | 0 PWMTMR3 period boundary not reached                                                                                                                                                                    |
|         |          | 1 PWMTMR3 period boundary reached                                                                                                                                                                        |
| 18      | TMR2PER  | PWMTMR2 Period Boundary Status.<br>The PWM_STAT.TMR2PER bit indicates whether or not the PWMTMR2 period boundary has been reached.                                                                       |
|         |          | 0 PWMTMR2 period boundary not reached                                                                                                                                                                    |
|         |          | 1 PWMTMR2 period boundary reached                                                                                                                                                                        |
| 17      | TMR1PER  | PWMTMR1 Period Boundary Status.<br>The PWM_STAT.TMR1PER bit indicates whether or not the PWMTMR1 period boundary has been reached.                                                                       |
|         |          | 0 PWMTMR1 period boundary not reached                                                                                                                                                                    |
|         |          | 1 PWMTMR1 period boundary reached                                                                                                                                                                        |
| 16      | TMR0PER  | PWMTMR0 Period Boundary Status.<br>The PWM_STAT.TMR0PER bit indicates whether or not the PWMTMR0 period boundary has been reached.                                                                       |
|         |          | 0 PWMTMR0 period boundary not reached                                                                                                                                                                    |
|         |          | 1 PWMTMR0 period boundary reached                                                                                                                                                                        |
| 11      | SRTRIPD  | Self-Restart Trip Status for Channel D.<br>The PWM_STAT.SRTRIPD bit indicates whether the PWM Channel D self-restart has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description. |
|         |          | 0 Channel D Self-Restart Trip Status is "not tripped"                                                                                                                                                    |
|         |          | 1 Channel D Self-Restart Trip Status is "tripped"                                                                                                                                                        |

**Table 18-9:** PWM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10      | FLTTRIPD | Fault Trip Status for Channel D.<br>The PWM_STAT.FLTTRIPD bit indicates whether the PWM Channel D fault has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description.              |
|         |          | 0 Channel D Fault Trip Status is "not tripped"                                                                                                                                                           |
|         |          | 1 Channel D Fault Trip Status is "tripped"                                                                                                                                                               |
| 9       | SRTRIPC  | Self-Restart Trip Status for Channel C.<br>The PWM_STAT.SRTRIPC bit indicates whether the PWM Channel C self-restart has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description. |
|         |          | 0 Channel C Self-Restart Trip Status is "not tripped"                                                                                                                                                    |
|         |          | 1 Channel C Self-Restart Trip Status is "tripped"                                                                                                                                                        |
| 8       | FLTTRIPC | Fault Trip Status for Channel C.<br>The PWM_STAT.FLTTRIPC bit indicates whether the PWM Channel C fault has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description.              |
|         |          | 0 Channel C Fault Trip Status is "not tripped"                                                                                                                                                           |
|         |          | 1 Channel C Fault Trip Status is "tripped"                                                                                                                                                               |
| 7       | SRTRIPB  | Self-Restart Trip Status for Channel B.<br>The PWM_STAT.SRTRIPB bit indicates whether the PWM Channel B self-restart has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description. |
|         |          | 0 Channel B Self-Restart Trip Status is "not tripped"                                                                                                                                                    |
|         |          | 1 Channel B Self-Restart Trip Status is "tripped"                                                                                                                                                        |

**Table 18-9:** PWM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | FLTTRIPB | Fault Trip Status for Channel B.<br>The PWM_STAT.FLTTRIPB bit indicates whether the PWM Channel B fault has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description.              |
|         |          | 0 Channel B Fault Trip Status is "not tripped"                                                                                                                                                           |
|         |          | 1 Channel A Fault Trip Status is "tripped"                                                                                                                                                               |
| 5       | SRTRIPA  | Self-Restart Trip Status for Channel A.<br>The PWM_STAT.SRTRIPA bit indicates whether the PWM Channel A self-restart has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description. |
|         |          | 0 Channel A Self-Restart Trip Status is "not tripped"                                                                                                                                                    |
|         |          | 1 Channel A Self-Restart Trip Status is "tripped"                                                                                                                                                        |
| 4       | FLTTRIPA | Fault Trip Status for Channel A.<br>The PWM_STAT.FLTTRIPA bit indicates whether the PWM Channel A fault has been tripped. For more information, see the PWM_TRIPCFG.MODE0A bit description.              |
|         |          | 0 Channel A Fault Trip Status is "not tripped"                                                                                                                                                           |
|         |          | 1 Channel A Fault Trip Status is "tripped"                                                                                                                                                               |
| 3       | RAWTRIP1 | Raw Trip 1 Status.<br>The PWM_STAT.RAWTRIP1 bit indicates the raw input level for the PWM TRIP1 input.                                                                                                   |
|         |          | 0 TRIP1 Level is Low                                                                                                                                                                                     |
|         |          | 1 TRIP1 Level is High                                                                                                                                                                                    |

**Table 18-9:** PWM\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                          |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | RAWTRIP0 | Raw Trip 0 Status.<br>The <code>PWM_STAT.RAWTRIP0</code> bit indicates the raw input level for the PWM TRIP0 input.                                              |
|         |          | 0      TRIP0 Level is Low                                                                                                                                        |
|         |          | 1      TRIP0 Level is High                                                                                                                                       |
| 1       | TRIP1    | Status bit set when TRIP1 is active low.<br>The <code>PWM_STAT.TRIP1</code> bit indicates whether the PWM TRIP1 fault has been tripped with an active-low input. |
|         |          | 0      TRIP1 status is "not tripped"                                                                                                                             |
|         |          | 1      TRIP1 status is "tripped" (active low)                                                                                                                    |
| 0       | TRIP0    | Status bit set when TRIP0 is active low.<br>The <code>PWM_STAT.TRIP0</code> bit indicates whether the PWM TRIP0 fault has been tripped with an active-low input. |
|         |          | 0      TRIP0 status is "not tripped"                                                                                                                             |
|         |          | 1      TRIP0 status is "tripped" (active low)                                                                                                                    |

## Interrupt Mask Register

The `PWM_IMSK` register masks (disables) or unmask (enables) PWM interrupts. When an unmasked interrupt occurs, the PWM latches the interrupt status in the `PWM_ILAT` register.

PWM\_IMSK: Interrupt Mask Register - R/W

Reset = 0x0000 0000

Chop Configuration Register

The PWM\_CHOPCFG register holds a divisor value that controls the chopping frequency. The PWM permits a mixing of the output signals with a high-frequency chopping signal to aid with interfacing to pulse transformers. Also note that high-frequency chopping may be independently enabled for each channel's high-side and the low-side outputs using channel control bits. (For example, control chopping for Channel A with the PWM\_CHANCFG.ENCHOPAH and PWM\_CHANCFG.ENCHOPAL bits.)

PWM\_CHOPCFG: Chop Configuration Register - R/W

Reset = 0x0000 0000

|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | <p>Gate Chopping Divisor.</p> <p>The PWM_CHOPCFG.VALUE bits provide the high frequency chopping divisor. When the divisor value is changed, the new period takes effect from the next edge of the chopping signal. The PWM_CHOPCFG.VALUE value may be calculated using either of the following formulas:</p> $\text{CHOPDIV} = [(T_{\text{CHOP}}/T_{\text{CK}}) / 4] - 1$ $\text{CHOPDIV} = [(f_{\text{CK}} / f_{\text{CHOP}}) / 4] - 1$ |

## Dead Time Register

The PWM\_DT register controls the dead time, which the PWM inserts into the pairs of output signals. Note that each channel has its own version of a double buffered dead time register, the double buffering of which depends on the period boundary of the PWMTMRx that the channel could be currently using. The dead time,  $T_d$ , is related to the value in the PWM\_DT register by:

$$T_d = \text{PWM\_DT} \times 2 \times t_{\text{CK}}$$

Note that the PWM holds the buffered PWM\_DT value for a channel at 0 if the channel's low side mode is independent (for example, PWM\_CHANCFG.MODELSA = 1). Also, note that the PWM\_DT value must be less than half the respective timer period (for example, PWM\_TMO/2). For more information about applying dead time to PWM output pairs, see the PWM Functional Description section.

| 9:0     | VALUE    | Dead Time.<br>The PWM_DT.VALUE bits select the dead time that the PWM adds to the timing of the output pairs. |

Sync Pulse Width Register

The PWM\_SYNC\_WID register selects the pulse width for the external sync pulse available on the PWM\_SYNC pin. The relation between the PWM\_SYNC\_WID register value and the pulse width ( $T_{PWM\_SYNC}$ ) is give by the formula:

$$PWM\_SYNC\_WID = (T_{PWM\_SYNC} / t_{CK}) - 1$$

For more information about applying the sync pulse width, see the PWM Functional Description section. Note that if the pulse width is changed in between sync pulses, the PWM applies the changed width on the next internal sync pulse. If, while the sync pulse is active, the chosen timer reaches its period boundary, the changed pulse width takes effect on that period boundary.

## Timer 0 Period Register

The PWM\_TM0 register controls the switch period ( $T_{SP}$  of the PWMTMR0 timer. The PWM\_TM0 value is in units of  $t_{CK}$  (the period of the peripheral clock) and the and is given by the formula:

$$PWM\_TM0 = (T_{SP}) / 2 \times t_{CK}$$

The value written to the register is effectively the number of  $t_{CK}$  clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM\_TM0 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

| 15:0    | VALUE    | Timer PWMTMR0 Period Value.<br>The PWM_TM0.VALUE bits select the period for the PWMTMR0 timer. |

## Timer 1 Period Register

The PWM\_TM1 register controls the switch period ( $T_{SP}$  of the PWMTMR1 timer. The PWM\_TM1 value is in units of  $t_{CK}$  (the period of the peripheral clock) and the and is given by the formula:

$$PWM\_TM1 = (T_{SP}) / 2 \times t_{CK}$$

The value written to the register is effectively the number of  $t_{CK}$  clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM\_TM1 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

| 15:0    | VALUE    | Timer PWMTMR2 Period Value.<br>The PWM_TM2.VALUE bits select the period for the PWMTMR2 timer. |

## Timer 3 Period Register

The PWM\_TM3 register controls the switch period ( $T_{SP}$  of the PWMTMR3 timer. The PWM\_TM3 value is in units of  $t_{CK}$  (the period of the peripheral clock) and the and is given by the formula:

$$PWM\_TM3 = (T_{SP}) / 2 \times t_{CK}$$

The value written to the register is effectively the number of  $t_{CK}$  clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM\_TM3 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

| 15:0    | VALUE    | Timer PWMTMR3 Period Value.<br>The PWM_TM3.VALUE bits select the period for the PWMTMR3 timer. |

Timer 4 Period Register

The PWM\_TM4 register controls the switch period ( $T_{SP}$  of the PWMTMR4 timer. The PWM\_TM4 value is in units of  $t_{CK}$  (the period of the peripheral clock) and the and is given by the formula:

$$PWM\_TM4 = (T_{SP}) / 2 \times t_{CK}$$

The value written to the register is effectively the number of  $t_{CK}$  clock increments in half the period of the respective timer. For more information about applying the switch period, see the PWM Functional Description section. Note that PWM\_TM4 values of 0 and 1 are not defined and must not be used when the PWM is enabled.

## Channel A Delay Register

The PWM\_DLYA register controls a delay for the Channel A timer (only PWMTMR1, PWMTMR2, PWMTMR3 or PWMTMR4) with reference to the main timer (PWMTMR0). To use apply this delay, the delay must be enabled (PWM\_CTL.DLYAEN =1}. For more information about applying the delay, see the PWM Functional Description section. Note that the PWM\_DLYA delay value must be less than twice the period value of the timer being used for the channel (for example, if PWMTMR1 is used, PWM\_DLYA must be less than 2xPWMTMR1). Also, note that the period of the main timer must be an integer multiple of the timer being used for the channel (for example, if PWMTMR1 is used, PWMTMR0 = NxPWMTMR1, where N is an integer).

Channel B Delay Register

The PWM\_DLYB register controls a delay for the Channel B timer (only PWMTMR1, PWMTMR2, PWMTMR3 or PWMTMR4) with reference to the main timer (PWMTMR0). To use apply this delay, the delay must be enabled (PWM\_CTL.DLYBEN =1}. For more information about applying the delay, see the PWM Functional Description section. Note that the PWM\_DLYB delay value must be less that less that twice the period value of the timer being used for the channel (for example, if PWMTMR1 is used, PWM\_DLYB must be less than 2xPWMTMR1). Also, note that the period of the main timer must be an integer multiple of the timer being used for the channel (for example, if PWMTMR1 is used, PWMTMR0 = NxPWMTMR1, where N is an integer).

## Channel C Delay Register

The `PWM_DLYC` register controls a delay for the Channel C timer (only `PWMTMR1`, `PWMTMR2`, `PWMTMR3` or `PWMTMR4`) with reference to the main timer (`PWMTMR0`). To use apply this delay, the delay must be enabled (`PWM_CTL.DLYCEN = 1`). For more information about applying the delay, see the PWM Functional Description section. Note that the `PWM_DLYC` delay value must be less than twice the period value of the timer being used for the channel (for example, if `PWMTMR1` is used, `PWM_DLYC` must be less than  $2 \times \text{PWMTMR1}$ ). Also, note that the period of the main timer must be an integer multiple of the timer being used for the channel (for example, if `PWMTMR1` is used,  $\text{PWMTMR0} = N \times \text{PWMTMR1}$ , where  $N$  is an integer).

| 9:8     | PULSEMODEHI | High Side Output Pulse Position.<br>The PWM_ACTL.PULSEMODEHI bits select the pulse position for Channel A high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the centre of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_AH0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the centre of the PWM period. This mode uses both the duty-cycle registers (PWM_AH0 and PWM_AH1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty-cycle registers (PWM_AH0 and PWM_AH1). |                         |
|         |             | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Symmetrical             |

## Channel A-High Duty-0 Register

The PWM\_AH0 and PWM\_AH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the high side output pulses for the Channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_ACTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_AH0 register to determine the assertion and de-assertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel A high pulse output for count less than PWM\_AH0 and de-asserts this output for count greater than PWM\_AH1.

The value range for the PWM\_AH0 and PWM\_AH1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_AH0 and PWM\_AH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_AH0 or PWM\_AH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

## Channel A-Low Duty-0 Register

The PWM\_AL0 and PWM\_AL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the low side output pulses for the Channel A duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_ACTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_AL0 register to determine the assertion and de-assertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel A low pulse output for count less than PWM\_AL0 and de-asserts this output for count greater than PWM\_AL1.

The value range for the PWM\_AL0 and PWM\_AL1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_AL0 and PWM\_AL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_AL0 or PWM\_AL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

## Channel B-High Duty-0 Register

The PWM\_BH0 and PWM\_BH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the high side output pulses for the Channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_BCTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_BH0 register to determine the assertion and de-assertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel B high pulse output for count less than PWM\_BH0 and de-asserts this output for count greater than PWM\_BH1.

The value range for the PWM\_BH0 and PWM\_BH1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_BH0 and PWM\_BH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_BH0 or PWM\_BH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

## Channel B-Low Duty-0 Register

The PWM\_BLO and PWM\_BL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the low side output pulses for the Channel B duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_BCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_BLO register to determine the assertion and de-assertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel B low pulse output for count less than PWM\_BLO and de-asserts this output for count greater than PWM\_BL1.

The value range for the PWM\_BLO and PWM\_BL1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_BLO and PWM\_BL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_BLO or PWM\_BL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

|---------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:10   | PULSEMODELO | Low Side Output Pulse Position.<br>The PWM_CCTL.PULSEMODELO bits select the pulse position for Channel C low side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the centre of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_CLO register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the centre of the PWM period. This mode uses both the duty-cycle registers (PWM_CLO and PWM_CL1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty-cycle registers (PWM_CLO and PWM_CL1). |
|         |             | 0 Symmetrical                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 9:8     | PULSEMODEHI | <p>High Side Output Pulse Position.</p> <p>The PWM_CCTL.PULSEMODEHI bits select the pulse position for Channel C high side output. In symmetrical mode, the channel forms a symmetrical pulse waveform around the centre of the PWM period. Only one of the duty cycle registers is used for an output in symmetrical mode. Note that in this mode, the values in the PWM_CH0 register is scaled, such that a value of 0 produces 50% duty. In asymmetrical mode, the channel forms an asymmetrical pulse waveform around the centre of the PWM period. This mode uses both the duty-cycle registers (PWM_CH0 and PWM_CH1). In left half or right half mode, the channel forms the pulse waveforms on either the first half (left) or the second half (right) of the PWM period. This mode uses both the duty-cycle registers (PWM_CH0 and PWM_CH1).</p> |

## Channel C-High Pulse Duty Register 0

The PWM\_CH0 and PWM\_CH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the high side output pulses for the Channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_CCTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_CH0 register to determine the assertion and de-assertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel C high pulse output for count less than PWM\_CH0 and de-asserts this output for count greater than PWM\_CH1.

The value range for the PWM\_CH0 and PWM\_CH1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_CH0 and PWM\_CH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_CH0 or PWM\_CH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

## Channel C-Low Pulse Duty Register 0

The PWM\_CL0 and PWM\_CL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the low side output pulses for the Channel C duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_CCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_CL0 register to determine the assertion and de-assertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel C low pulse output for count less than PWM\_CL0 and de-asserts this output for count greater than PWM\_CL1.

The value range for the PWM\_CL0 and PWM\_CL1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_CL0 and PWM\_CL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_CL0 or PWM\_CL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

## Channel D-High Duty-0 Register

The PWM\_DHO and PWM\_DH1 registers determine the width for the high side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the high side output pulses for the Channel D duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_DCTL.PULSEMODEHI bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_DHO register to determine the assertion and de-assertion count for the high side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel D high pulse output for count less than PWM\_DHO and de-asserts this output for count greater than PWM\_DH1.

The value range for the PWM\_DHO and PWM\_DH1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_DHO and PWM\_DH1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_DHO or PWM\_DH1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

**Table 18-41:** PWM\_DH1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | DUTY     | Duty Cycle De-Asserted Count.<br>The PWM_DH1.DUTY bits select the duty cycle de-asserted count for Channel D high side output. |

## Channel D-Low Pulse Duty Register 0

The PWM\_DL0 and PWM\_DL1 registers determine the width for the low side output pulses. The values in these registers select the assertion count (in terms of  $t_{CK}$ ) of the low side output pulses for the Channel D duty cycle.

The operation of the duty-cycle registers varies, depending on the pulse mode selected with the PWM\_DCTL.PULSEMODELO bits. When the pulse mode is symmetrical, the PWM uses the value in the PWM\_DL0 register to determine the assertion and de-assertion count for the low side output pulses. When the pulse mode is asymmetrical, left half, or right half, the PWM asserts Channel D low pulse output for count less than PWM\_DL0 and de-asserts this output for count greater than PWM\_DL1.

The value range for the PWM\_DL0 and PWM\_DL1 registers depends on the period of the timer being used by the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2$  (two's complement) and  $+PWM\_TMO/2$ , when dead time (PWM\_DT) is not considered.

When dead time is considered for symmetrical and asymmetrical pulse modes, the value range for PWM\_DL0 and PWM\_DL1 depends on the period of the time being used by the channel and the amount of dead time applied to the channel. For example, if PWM\_TMO is used, the duty cycle values may be between  $-PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $+PWM\_TMO/2 + PWM\_DT$ .

When dead time is considered for left half or right half pulse modes, if PWM\_TMO is used, the duty cycle values may be between  $PWM\_TMO/2 + PWM\_DT$  (two's complement) to  $-PWM\_TMO/2 - PWM\_DT$ .

Note that using values in the PWM\_DL0 or PWM\_DL1 registers that fall outside these limits causes PWM over or under modulation.

For more information about pulse modes and duty cycle selection, see the Functional Description section.

# 19 Universal Async Rx/Tx (UART)

This chapter describes the Universal Asynchronous Receiver/Transmitter (UART) modules.

The UART modules are full-duplex peripherals compatible with PC-style industry-standard UARTs. The UARTs convert data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word length, stop bits, bit rate, and parity generation options. The UARTs include interrupt-handling hardware. Interrupts can be generated from multiple events.

The UARTs are logically compliant to EIA-232E, EIA-422, EIA-485 and LIN standards, but usually require external transceiver devices to meet electrical requirements. In IrDA (Infrared Data Association) mode, the UARTs meet the half-duplex IrDA SIR (9.6/115.2 Kbps rate) protocol. In multi-drop bus mode, the UARTs meet the full-duplex MDB/ICP v2.0 protocol.

Partial modem status and control functionality is supported by the UART module to allow for hardware flow control.

The UARTs are DMA-capable peripherals with support for separate transmit and receive DMA master channels. They can be used in either DMA or programmed core mode of operation. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention as the DMA engine itself moves the data. Each UART has its own separate transmit and receive DMA channels.

One of the peripheral timers can be used to provide a hardware-assisted auto-baud detection mechanism for use with the UART. The timers are external to the UART.

## UART Features

Each UART includes the following features.

- 5–8 data bits
- Programmable extra stop bit and programmable extra half-stop bit
- Even, odd, and sticky parity bit options
- Additional 8-stage receive FIFO with programmable threshold interrupt
- Flexible transmit and receive interrupt timing
- 3 interrupt outputs for receive, transmit, and status
- Independent DMA operation for receive and transmit

- Programmable automatic RTS/CTS hardware flow control
- False start bit detection
- SIR IrDA operation mode
- MDB/ICP v2.0 operation mode
- Internal loop back
- Improved bit rate granularity
- LIN break command/Inter-frame gap transmission support

**Table 19-1:** UART Specifications

| Feature                  | Availability      |
|--------------------------|-------------------|
| Protocol                 |                   |
| Master-Capable           | Yes               |
| Slave-Capable            | Yes               |
| Transmission Simplex     | Yes               |
| Transmission Half-Duplex | Yes               |
| Transmission Full-Duplex | Yes               |
| Access Type              |                   |
| Data Buffer              | Yes               |
| Core Data Access         | Yes               |
| DMA Data Access          | Yes               |
| DMA Channels             | 2 (per UART Port) |
| DMA Descriptor           | Yes               |
| Boot Capable             | Yes (Slave Mode)  |
| Local Memory             | No                |
| Clock Operation          | SCLK/16           |

## UART Functional Description

The following sections provide details on the UART's functionality.

### UART Register List

The universal asynchronous receiver/transmitter (UART) module is a full-duplex peripheral compatible with PC-style industry-standard UARTs. The UARTs convert data between serial and parallel formats. The serial communication follows an asynchronous protocol that supports various word length, stop bits, and parity generation options. The UARTs include interrupt-handling hardware. Interrupts can be generated from multiple events. A set of registers govern UART operations. For more information on UART functionality, see the UART register descriptions.

**Table 19-2:** UART Module Registers

| Name          | Description                            |
|---------------|----------------------------------------|
| UART_REVID    | Revision ID Register                   |
| UART_CTL      | Control Register                       |
| UART_STAT     | Status Register                        |
| UART_SCR      | Scratch Register                       |
| UART_CLK      | Clock Rate Register                    |
| UART_IMSK     | Interrupt Mask Register                |
| UART_IMSK_SET | Interrupt Mask Set Register            |
| UART_IMSK_CLR | Interrupt Mask Clear Register          |
| UART_RBR      | Receive Buffer Register                |
| UART_THR      | Transmit Hold Register                 |
| UART_TAIP     | Transmit Address/Insert Pulse Register |
| UART_TSR      | Transmit Shift Register                |
| UART_RSR      | Receive Shift Register                 |
| UART_TXCNT    | Transmit Counter Register              |
| UART_RXCNT    | Receive Counter Register               |

## UART Block Diagram

The following figure shows a simplified block diagram of one UART module and how it interconnects to the processor system.

**Figure 19-1:** UART Block Diagram

## UART Architectural Concepts

The following sections provide information about the UART architecture.

## Internal Interface

The UART is a DMA-capable peripheral with support for separate TX and RX DMA master channels. It can be used in either DMA or programmed core modes of operation. The core mode requires software management of the data flow using either interrupts or polling. The DMA method requires minimal software intervention, as the DMA engine itself moves the data.

All UART registers are 32 bits wide. They connect to the peripheral MMR bus. All the bits of all the MMRs may not be used; unused bits are zero-filled. The `UART_RBR` and `UART_THR` registers also connect to one of the P2P buses (8-bit data width).

Each UART has three interrupt outputs. The transmit request and receive request outputs can function as DMA requests and connect to the DMA controller. Therefore, if the DMA is not enabled, the DMA controller simply forwards the request to the system event controller (SEC). The status interrupt output connects directly to the SEC. On many processors, the `UART_RX` pin is also sensed by the alternative capture input (`TMR_AUX_IN`) of one of the GP timers. When configured in capture mode, the GP Timer can then be used to detect the bit rate of the received signal.

## External Interface

Each UART features an `UART_RX` (receive) and an `UART_TX` (transmit) pin available through the general-purpose ports. These two pins usually connect to an external transceiver device that meets the electrical requirements of full duplex (for example, EIA-232, EIA-422, 4-wire EIA-485) or half duplex (for example, 2-wire EIA-485, LIN) standards. Additionally, the UART features a pair of `UART_CTS` (clear to send, input) and `UART_RTS` (request to send, output) pins for hardware flow control. UART signals are usually multiplexed with other functions at the pin level.

## Hardware Flow Control

To prevent the UART transmitter from sending data while the receiving counterpart is not ready, a RTS/CTS hardware flow control mechanism is supported. The RTS signal is an output that connects to the communication partner's CTS input. If data transfer is bidirectional, the handshake is as shown below.

**Figure 19-2:** UART Hardware Flow

Regardless of using DMA or core mode, the receiver can de-assert the `RTS` signal to indicate that its receive buffer is getting full. Further data may cause an overrun error. Consequently, the transmitter pauses when the `CTS` input is in a de-asserted state. If the `UART_CTS` pin is de-asserted, the transmitter still completes transmission of the data currently held in the `UART_TSR` register, but it does not continue with the data in the `UART_THR` register. If the `UART_CTS` pin is asserted again, the transmitter resumes and loads the content of `UART_THR` register into the `UART_TSR` register.

## UART Bit Rate Generation

The sample clock is characterized by the peripheral clock (`SCLK0`) and the 16-bit divisor in the `UART_CLK` register. The UART clock is enabled by the `UART_CTL.EN` bit. By default every serial bit is oversampled 16 times. The bit clock is 1/16th of the sample clock. If not in IrDA mode, the bit clock can equal the sample clock if the `UART_CLK.EDBO` bit is set, so that the following applies:

$$BIT\ RATE = \frac{SCLK0}{16^{(1-EDBO)} \times Divisor}$$

**Figure 19-3:** Bit Rate Equation

The following table provides example divide factors required to support standard baud rates at a `SCLK0` of 125 MHz.

**Table 19-6:** UART Bit Rate Examples With 125 MHz `SCLK0`

| Bit Rate  | D factor = 16 |              |         | D factor = 1 |              |         |
|-----------|---------------|--------------|---------|--------------|--------------|---------|
|           | DL            | Actual       | % Error | DL           | Actual       | % Error |
| 2,400     | 3,255         | 2,400.15     | 0.006   | 52,083       | 2,400.02     | 0.001   |
| 4,800     | 1,628         | 4,798.83     | 0.024   | 26,042       | 4,799.94     | 0.001   |
| 9,600     | 814           | 9,597.67     | 0.024   | 13,021       | 9,599.88     | 0.001   |
| 19,200    | 407           | 19,195.33    | 0.024   | 6,510        | 19,201.23    | 0.006   |
| 38,400    | 203           | 38,485.22    | 0.022   | 3,255        | 38,402.46    | 0.006   |
| 57,600    | 136           | 57,444.85    | 0.269   | 2,170        | 57,603.69    | 0.006   |
| 115,200   | 68            | 114,889.71   | 0.269   | 1,085        | 115,207.37   | 0.006   |
| 921,600   | 8             | 976,562.50   | 5.964   | 136          | 919,117.65   | 0.269   |
| 1,500,000 | 5             | 1,562,500.00 | 4.167   | 83           | 1,516,021.10 | 0.402   |

**Table 19-6:** UART Bit Rate Examples With 125 MHz SCLK0 (Continued)

| Bit Rate  | D factor = 16 |              |         | D factor = 1 |              |         |
|-----------|---------------|--------------|---------|--------------|--------------|---------|
|           | DL            | Actual       | % Error | DL           | Actual       | % Error |
| 3,000,000 | 3             | 2,604,166.67 | 13.194  | 42           | 2,976,190.48 | 0.794   |
| 6,250,000 | 1             | 7,812,500.00 | 25.000  | 20           | 6,250,000.00 | 0.000   |

**NOTE:** Careful selection of SCLK0 frequencies—that is, even multiples of desired bit rates— can result in lower error percentages.

Setting the bit clock equal to the sample clock (UART\_CLK.EDB0 =1) improves bit rate granularity and enables the bit clock to more closely match the bit rate of the communication partner. There is, however, a disadvantage—the power dissipation is higher. Also the sample points may not be that accurate. Therefore, it is recommended to use UART\_CLK.EDB0 =1 mode only when bit rate accuracy is not acceptable in UART\_CLK.EDB0 =0 mode.

The UART\_CLK.EDB0 =1 mode is not intended to increase operation speed beyond the electrical limitations of the UART transfer protocol.

## Autobaud Detection

At the chip level, the UART RX pin is usually routed to an alternate capture input (TMR\_AUX\_IN) of a general purpose timer. When working in Width Capture mode, this general-purpose timer can be used to automatically detect the bit rate applied to the RX pin by an external device. The capture capabilities of the timer are often used to supervise the bit rate at runtime. If the UART was talking to any device supplied by a weak clock oscillator that drifts over time, the processor can then readjust its UART bit rate dynamically as required.

Often, autobaud detection is used for initial bit rate negotiations. There, the processor is most likely a slave device waiting for the host to send a predefined autobaud character. This is a common scenario for UART booting. In this scenario, it is recommended that the UART\_CTL.EN bit is not enabled while autobaud detection is performed, to prevent the UART from starting reception with incorrect bit rate matching. Alternatively, the UART can be disconnected from its RX pin by setting the UART\_CTL.LOOP\_EN bit.

A software routine can detect the pulse widths of serial stream bit cells. Because the sample base of the timer is synchronous with the UART operation—all derived from the same SCLK0—the pulse widths can be used to calculate the bit rate divider for the UART by using the following formula.

$$DIVISOR = \frac{TIMER\_TMR\_WID}{16^{(1-EDB0)} \times \text{Number of captured UART bits}}$$

**Figure 19-4:** UART Bit Rate Divider Calculation

In order to increase the number of timer counts and therefore the resolution of the captured signal, it is recommended not to measure just the pulse width of a single bit, but to enlarge the pulse of interest over more bits. Traditionally, a NULL character (ASCII 0x00) is used in autobaud detection, as shown below.

**Figure 19-5:** Autobaud Detection

Because the example frame encloses 8 data bits and 1 start bit, apply the following formula.

$$DIVISOR = \frac{TIMER\_TMR\_WID}{16^{(1-EDB0)} \times 9}$$

**Figure 19-6:** Autobaud Detection (8 Data Bits, 1 Start Bit)

Real RX signals often have asymmetrical falling and rising edges, and the sampling logic level is not exactly in the middle of the signal voltage range. At higher bit rates, such pulse-width-based autobaud detection might not return adequate results without additional analog signal conditioning. Measuring signal periods works around this issue and is strongly recommended.

For example, predefine ASCII character “@” (0x40) as the autobaud detection character and measure the period between two subsequent falling edges. As shown in the figure below, measure the period between the falling edge of the start bit and the falling edge after bit 6. Since this period encloses 8 bits, apply the following formula.

$$DIVISOR = \frac{TIMER\_TMR\_PER}{16^{(1-EDB0)} \times 8}$$

**Figure 19-7:** Autobaud Detection (8 Bits)

Or:

- Divisor = `TIMER_TMR_PER >> 7` if `UART_CLK.EDB0 = 0`
- Divisor = `TIMER_TMR_PER >> 3` if `UART_CLK.EDB0 = 1`

The following figure shows the ASCII “@” (0x40) detection character.

**Figure 19-8:** Autobaud Detection Character 0x40

## UART Debug Features

The UART has the option to automatically calculate and transmit a parity bit. The following table summarizes parity behavior assuming 8-bit data words (`UART_CTL.WLS = b#11`).

**Table 19-7:** UART Parity

| PEN | STP | EPS | Data (hex) | Data (binary, LSB first) | Parity |
|-----|-----|-----|------------|--------------------------|--------|
| 0   | x   | x   | x          | x                        | None   |
| 1   | 0   | 0   | 0x60       | 0000 0110                | 1      |
| 1   | 0   | 0   | 0x57       | 1110 1010                | 0      |
| 1   | 0   | 1   | 0x60       | 0000 0110                | 0      |
| 1   | 0   | 1   | 0x57       | 1110 1010                | 1      |
| 1   | 1   | 0   | x          | x                        | 1      |
| 1   | 1   | 0   | x          | x                        | 1      |
| 1   | 1   | 1   | x          | x                        | 0      |
| 1   | 1   | 1   | x          | x                        | 0      |

The two force error bits, `UART_CTL.FPE` and `UART_CTL.FFE`, are intended for test purposes. They are useful for debugging software, especially in loop back mode.

The UART can be set to internal loop back mode (`UART_CTL.LOOP_EN = 1`). Loop back mode disconnects the receiver's input from the RX pin and internally redirects the transmit output to the receiver. The TX pin remains active and continues to transmit data externally as well. Loop back mode also forces the `UART_RTS` pin to de-assert, disconnects the CTS bit from the `UART_CTS` input pin, and connects the internal version of `UART_RTS` to the `UART_STAT.CTS` bit.

Additionally, the TX pin can be forced to zero asynchronously through the `UART_CTL.SB` bit.

## UART Operating Modes

The UART's main operating modes are UART Mode, IrDA SIR Mode, and MDB Mode.

## UART Mode

The UART Mode follows an asynchronous serial communication protocol with these options:

- 1 start bit
- 5-8 data bits
- Address bit
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits valid only in 5-bit word length)

The format of received and transmitted character frames is controlled by the `UART_CTL` register. Data is always transmitted and received with the least significant bit (LSB) first.

The following figure shows a typical physical bit stream measured on a TX pin.

**Figure 19-9:** Bit stream on a UART TX Pin Transmitting an “S” Character (0x53)

## IrDA SIR Mode

Aside from the standard UART functionality, the UART also supports serial data communication by way of infrared signals, according to the recommendations of the Infrared Data Association (IrDA). The physical layer known as IrDA SIR (9.6/115.2 Kbps rate) is based on return-to-zero-inverted (RZI) modulation. Pulse position modulation is not supported.

Using the 16x data rate clock, RZI modulation is achieved by inverting and modulating the non-return-to-zero (NRZ) code normally transmitted by the UART. On the receive side, the 16x clock is used to determine an IrDA pulse sample window, from which the RZI modulated NRZ code is recovered.

**NOTE:** The `UART_CLK.EDB0` bit is not valid in IrDA mode—this bit should be cleared (= 0) in this mode.

## MDB Mode

The Multi-Drop Bus (MDB) mode is very similar to the UART mode, but also includes support for an Address (or Mode) bit. With the addition of the Address bit, the UART can provide hardware support for the Multi-Drop Bus/Internal Communication Protocol (MDB/ICP v2.0).

In multi-drop bus mode, the address bit is used to indicate if the transferred word is an address word or a data word. An address bit of 1 signifies an address word and requires all slave devices to read the word. An address bit of 0 signifies a data word and only the slave that is being addressed needs to read the word.

The address bit is similar to the parity bit in the sense that it is not part of the data word, but is appended to the transmitted data word by the hardware. Therefore, a write to the `UART_THR/UART_TAIP` registers requires writing only the data word. A read from `UART_RBR` returns only the data word, the `UART_STAT.ADDR` bit contains the address bit corresponding to the word in the `UART_RBR` register.

The MDB mode follows an asynchronous serial communication protocol with the following options.

- 1 start bit
- 5-8 data bits
- Address bit
- None, even, odd or sticky parity
- 1, 1½, or 2 stop bits (1½ stop bits valid only in 5-bit word length)

**NOTE:** If the address bit and parity bit are both enabled, the parity check and generation includes the address bit in its parity calculation.

## UART Data Transfer Modes

The UART is capable of transferring data using both the core and DMA. Receive and transmit paths operate completely independently except that the bit rate and the frame format are identical for both transfer directions. Transmit and receive channels are both buffered. The `UART_THR` register buffers the transmit shift register (`UART_TSR`) and the `UART_RBR` register buffers the receive shift register (`UART_RSR`).

## UART Mode Transmit Operation (Core)

In core mode, data is moved to and from the UART by the processor core. A write to the `UART_THR` register initiates the transmit operation. If no former operation is pending, the data is immediately passed from the `UART_THR` register to the `UART_TSR` register. There, it is shifted out at the bit rate characterized by the `UART_CTL` register, with start, stop, and parity bits appended as defined by the `UART_CTL` register. The `UART_THR` register and the `UART_TSR` register can be modeled as a two-stage transmit buffer. The least significant bit (LSB) is always transmitted first. This is bit 0 of the value written to `UART_THR`.

## UART Mode Break Command and Inter-Frame Gap Transmit Operation

Break Command/Inter-frame gap functionality is available only in UART mode. The `UART_TAIP` register has different functionality in other modes. Break command/Inter-frame gap transmission is initiated by writes to the `UART_TAIP` register. If no former transmit operation is pending (in the `UART_TSR` register), a pulse is transmitted for the duration specified by `UART_TAIP[6-0]`/bit rate, where bit rate is set by the `UART_CLK` register. The polarity of this pulse is set by bit 7 in the `UART_TAIP` register.

**NOTE:** The `UART_CTL.TPOLC` setting, if enabled, could lead to an inverted most-significant bit being transmitted.

**NOTE:** If other transmission is pending (in the `UART_TSR` register), the `UART_TAIP` initiated pulse is queued until after all pending operations have finished and all stop bits are transmitted.

The transmission of break command/inter-frame gap is followed by transmission of the number of stop bits as set in the `UART_CTL.STB` and `UART_CTL.STBH` bit fields.

## UART Mode Receive Operation (Core)

The receive operation uses the same data format as the transmit configuration, except that one valid stop bit is always sufficient; that is, the `STB` bit and `STBH` bit have no impact to the receiver.

The UART receiver senses the falling edges of the RX input. When an edge is detected, the receiver starts sampling the input according to settings in the `UART_CLK` register. The start bit is sampled (majority sampling) close to its midpoint. If sampled low, a valid start condition is assumed. Otherwise, the detected falling edge is discarded.

After detection of the start bit, the received word is shifted into the `UART_RSR` register.

After the corresponding stop bit is received, the content of the `UART_RSR` register is transferred to the 8-deep receive FIFO and is accessible by reading the `UART_RBR` register.

The receive FIFOs and the `UART_RBR` register can be seen as a 9-stage receive buffer. If the stop bit of the 9th word is received before software reads the `UART_RBR` register, an overrun error is reported. The overrun case protects data in the `UART_RBR` and the receive FIFO from being overwritten by further data until the OE bit is cleared by software. The data in the `UART_RSR` register, however, is immediately destroyed as soon as the overrun occurs.

The sampling clock is 16 times faster than the bit clock. The receiver over samples every bit 16 times and makes a majority decision based on the middle three samples. This improves immunity against noise and hazards on the line. Spurious pulses of less than two times the sampling clock period are disregarded.

Normally, every incoming bit is sampled at exactly the 7th, 8th and 9th sample clock. If, however, the `UART_CLK.EDBO` bit is set to 1 to achieve better bit rate granularity and accuracy as required at high operation speeds, the bits are one roughly sampled at 7/16th, 8/16th and 9/16th of their period. Hardware design should ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

Reception is started when a falling edge is detected on the RX input pin. The receiver attempts to see a start bit. The data is shifted into the `UART_RSR` register. After the 9th sample of the first stop bit is processed, the received data is copied to the 8-stage receive FIFO and the `UART_RSR` recovers for further data reception.

The receiver samples data bits close to their midpoint. Because the receiver clock is usually asynchronous to the transmitter's data rate, the sampling point may drift relative to the center of the data bits. The sampling point is synchronized again with each start bit, so the error accumulates only over the length of a single word. The polarity of received data is selectable, using the `UART_CTL.RPOLC` bit.

**NOTE:** The receiver checks for only a single stop bit. After the third sample of the first stop bit has been received (at time 9/16th of the stop bit duration), the receiver immediately takes action (status update) and prepares itself for new falling edge detection (start detection).

## IrDA Transmit Operation

To generate the IrDA pulse transmitted by the UART, the normal NRZ output of the transmitter is first inverted if the `UART_CTL.TPOLC` bit is configured for active-low operation, such that a 0 is transmitted as a high pulse of 16 UART clock periods and a 1 is transmitted as a low pulse for 16 UART clock periods. The leading edge of the pulse is then delayed by six UART clock periods. Similarly, the trailing edge of the pulse is truncated by eight UART clock periods. For a 16-cycle UART clock period, this results in the final representation of the original 0 as a high pulse of only 3/16 clock periods. The pulse is centered around the middle of the bit time, as shown in the figure below. The final IrDA pulse is fed to the off-chip infrared driver.

This modulation approach ensures a pulse width output from the UART of three cycles high out of every 16 UART clock cycles. As shown in the figure below, the error terms associated with the bit rate generator are very small and well within the tolerance of most infrared transceiver specifications.

**NOTE:** In IrDA mode, writes to the `UART_TAIP` register are equivalent to writes to the `UART_THR` register.

Figure 19-10: IrDA Transmit Pulse

## IrDA Receive Operation

The IrDA receiver function is more complex than the transmit function. The receiver must discriminate the IrDA pulse and reject noise. To do this, the receiver looks for the IrDA pulse in a narrow window centered around the middle of the expected pulse.

Glitch filtering is accomplished by counting 16 system clocks from the time an initial pulse is seen. If the pulse is absent when the counter expires, it is considered a glitch. Otherwise, it is interpreted as a 0. This is acceptable because glitches originating from on-chip capacitive cross-coupling typically do not last for more than a fraction of the system clock (SCLK0) period. Sources outside of the chip and not part of the transmitter can be avoided by appropriate shielding. The only other source of a glitch is the transmitter itself. The processor relies on the transmitter to perform within specification. If the transmitter violates the specification, unpredictable results may occur. The 4-bit counter adds an extra level of protection at a minimal cost.

**NOTE:** Because SCLK0 can change across systems, the longest glitch tolerated is inversely proportional to the SCLK0 frequency.

The receive sampling window is determined by a counter that is clocked at the 16x bit-time sample clock. The sampling window is re-synchronized with each start bit by centering the sampling window around the start bit.

The polarity of receive data is selectable, using the `UART_CTL.RPOLC` bit. The following figure provides examples of each polarity type.

**Figure 19-11:** IrDA Receiver Pulse Detection

## MDB Transmit Operation

In MDB mode, receive and transmit paths operate completely independently from each other, except for sharing bit rate and frame formats for both transfer directions.

Transmit operation is initiated by writing the `UART_THR` or `UART_TAIP` registers. A write to the `UART_THR` register transmits the written word with the appending address bit set low, a write to the `UART_TAIP` register transmits the written word with the appended address bit set high. The data is moved into the `UART_TSR` register, where it is shifted out at the bit rate programmed by the `UART_CLK` register, with start, stop, address, and parity bits appended as required.

If DMA is enabled, the DMA engine always writes the data into the `UART_THR` register, and the written word is transmitted with the appending address bit set low.

The polarity of transmit data is selectable, using the `UART_CTL.TPOLC` bit.

## MDB Receive Operation

Receive operations use the same data format as the transmit configuration, except that the number of stop bits is always assumed to be 1. After detection of the start bit, the received word is shifted into the `UART_RSR` register at the programmed bit.

Normally, every incoming bit is sampled at exactly the 7th, 8th and 9th sample clock. If, however, the `UART_CLK.EDBO` bit is set to achieve better bit rate granularity and accuracy as required at high operation speeds, the bits are roughly sampled at 7/16th, 8/16th and 9/16th of their period. Hardware design should ensure that the incoming signal is stable between 6/16th and 10/16th of the nominal bit period.

After the appropriate number of bits (including address, parity, and stop bits) is received, the `UART_RSR` register is transferred to the receive FIFO and accessible through the `UART_RBR` register.

The polarity of receive data is selectable, using the `UART_CTL.RPOLC` bit.

## DMA Modes

In DMA modes, separate receive and transmit DMA channels move data between the UART and memory. The software does not have to move data; it just has to set up the appropriate transfers either through the descriptor mechanism or through autobuffer mode.

DMA channels provide a 4-deep FIFO, resulting in total buffer capabilities of 6 words at the transmit side and 9 words at the receive side. In DMA mode, the latency is determined by the bus activity and arbitration mechanism and not by the processor loading and interrupt priorities.

To enable UART DMA, first set up the system DMA control registers and then enable the `UART_IMSK.ERBFI` and/or `UART_IMSK.ETBEI` interrupts. This is necessary because these interrupt request lines double as DMA request lines. With DMA enabled, once these requests are received, the DMA control unit generates a direct memory access. If DMA is not enabled, the UART interrupt is passed on to the system interrupt handling unit.

**NOTE:** The UART's status interrupt goes directly to the system interrupt handling unit, bypassing the DMA unit completely.

For transmit DMA, programs should set the `SYNC` bit in the `DMAx_CFG` register. With this bit set, interrupt generation is delayed until the entire DMA FIFO is drained to the UART module. The UART TX DMA interrupt service routine is allowed to disable the DMA or to clear the `ETBEI` control bit only when the `SYNC` bit is set, otherwise up to four data bytes might be lost.

When the `ETBEI` bit is set in the `UART_IMSK` register, an initial transmit DMA request is issued immediately. The program should then clear the `ETBEI` bit through the DMA service routine.

In DMA transmit mode, the `ETBEI` bit enables the peripheral request to the DMA FIFO. The strobe on the memory side is still enabled by the `DMA_CFG.EN` bit. If the DMA count is less than the DMA FIFO depth, which is 4, then the DMA interrupt might be requested before the `ETBEI` bit is set. If this behavior is not wanted, set the `SYNC` bit in the `DMAx_CONFIG` register.

Regardless of the `DMAx_CONFIG.SYNC` setting, the DMA stream has not left the UART transmitter completely at the time the interrupt is generated. Transmission may abort in the middle of the stream, causing data loss, if the UART clock was disabled without additional synchronization with the `TEMT` bit.

The UART provides functionality to avoid resource consuming polling of the `TEMT` bit. The `EDTPTI` bit in the `UART_IMSK_SET` register enables the `TEMT` bit to trigger a DMA interrupt. To delay the DMA completion interrupt until the last data word of a STOP DMA has left the UART, keep the `DMA_CFG.DI_EN` bit cleared and set the `EDTPTI` bit instead. Then, the normal DMA completion interrupt is suppressed. Later, the `TEMT` event triggers a DMA interrupt after the DMA's last word has left the UART transmit buffers. If `DI_EN` and `EDTPTI` are set, when finishing STOP mode, the DMA requests two interrupts.

The UART's DMA supports 8-bit and 16-bit operation, but not 32-bit operation. Sign extension is not supported.

## Mixing DMA and Core Modes

Especially on the transmit side, switching from DMA mode to core operation on the fly requires some consideration. By default, the interrupt timing of the DMA is synchronized with the memory side of the DMA FIFOs. Normally, the TX DMA completion interrupt is generated after the last byte is copied from the memory into the DMA FIFO. The TX DMA interrupt service routine is not yet permitted to disable the `DMA_CFG.EN` bit. The interrupt is requested by the time the `DMA_STAT.DONE` bit is set. The `DMA_STAT.RUN` bit, however, remains set until the data has completely left the transmit DMA FIFO.

Therefore, when planning to switch from a DMA to the core mode, always set the `SYNC` bit in the `DMA_CFG` word of the last descriptor or work unit before handing over control to core mode. Then, after the interrupt occurs, software can write new data into the `UART_THR` register as soon as the `THRE` bit permits. If the `SYNC` bit cannot be set, software can poll the `DMA_STAT.RUN` bit instead. Using the `EDTPTI` bit can avoid expensive status bit polling, alternatively.

When switching from core to DMA operation, take care that the very first DMA request is issued properly. If the DMA is enabled while the UART is still transmitting, no precaution is required. If, however, the DMA is enabled after the `TEMT` bit is high, the `ETBEI` bit should be pulsed to initiate DMA transmission.

## Setting Up Hardware Flow Control

Use the following steps to setup UART hardware flow control:

1. Configure automatic or manual hardware flow control for the receiver through the `UART_CTL.ARTS` bit, and/or the transmitter through the `UART_CTL.ACTS` bit.
2. Configure CTS and RTS polarity through the `UART_CTL.FCPOL` bit.

*AFTER COMPLETING THIS TASK:*

On reset, when the UART is not yet enabled and the port multiplexing has not been programmed, the `RTS` pin is not driven. Some applications may require the `RTS` signal to be pulled to either state by a resistor during reset.

## UART Event Control

Status flags in the `UART_STAT` register are available to signal data reception, parity, and error conditions, if required.

### Interrupt Masks

Each UART features a set of Interrupt Mask Registers: `UART_IMSK`, `UART_IMSK_SET`, and `UART_IMSK_CLR`. The `UART_IMSK` register supports read/write operations. Writing ones to the `UART_IMSK_SET` register enables interrupts, writing ones to the `UART_IMSK_CLR` register disables them. Reads from either register return the enabled bits. This way, different interrupt service routines can control transmit, receive, and status interrupts independently and easily.

The `UART_IMSK` registers are used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the `UART_IMSK.ERBFI` and/or `UART_IMSK.ETBEI` bits in this register are normally set.

Each UART module has three interrupt outputs. One is dedicated for transmission, one for reception, and the third is used to report status events. Transmit and receive requests are routed through the DMA controller. The status request goes directly to the system event controller (SEC).

If the associated DMA channel is enabled, the request functions as a DMA request. If the DMA channel is disabled, it simply forwards the request to the SEC. Note that a DMA channel must be associated with the UART module to enable TX and RX interrupts. Otherwise, transmit and receive requests cannot be forwarded.

**NOTE:** To operate in interrupt mode without using DMA channels, set the `UART_IMSK.ELSI` bit. This redirects receive and transmit requests to the status interrupt output. The status interrupt goes directly to the SEC without being routed through the DMA controller

### Interrupt Servicing

UART writes and reads can be accomplished through interrupt service routines (ISRs). Separate interrupt lines are provided for TX, RX, and status. The independent interrupts can be enabled individually by the `UART_IMSK` register group. The `UART_CTL.EN` bit must be set to enable UART transmit interrupts.

The ISRs can evaluate the status bits in the `UART_STAT` register to determine the signaling interrupt source. Interrupts must also be assigned and unmasked by the processor's system event controller. The ISRs must clear the interrupt latches explicitly. To reduce interrupt frequency on the receive side in core mode, the `UART_IMSK.ERFCI` status interrupt may be used as an alternative to the regular `UART_IMSK.ERBFI` receive interrupt. Hardware must ensure that at least two (if `UART_CTL.RFIT=0`) or four (if `UART_CTL.RFIT=1`) words are available in the receive buffer by the time the interrupt is requested.

## Transmit Interrupts

Transmit interrupts are enabled by the `UART_IMSK_SET.ETBEI` bit.

The `UARTx_THR` and `UARTx_TAIP` registers are the same physical register, and both affect the signaling of the `UART_STAT.TEMT`, `UART_STAT.TFI`, and `UART_STAT.THRE` bits similarly.

**Figure 19-12:** Transmit Interrupts

The transmit request is asserted along with the `UART_STAT.THRE` bit, indicating that the TX buffer is ready for new data. Note that the `UART_STAT.THRE` bit resets to 1. When the `UART_IMSK_SET.ETBEI` bit is set, the UART module immediately issues an interrupt or DMA request. This way, no special handling of the first character is required when transmission of a string is initiated. Simply set the `UART_IMSK_SET.ETBEI` bit and let the interrupt service routine load the first character from memory and write it to the `UART_THR` register in the normal manner. Accordingly, the `UART_IMSK.ETBEI` bit can be cleared through the `UART_IMSK_CLR` register if the string transmission has completed.

The `UART_STAT.THRE` bit is cleared by hardware when new data is written to the `UARTx_THR` register. These writes also clear the TX interrupt request. However, they also initiate further transmission. If software doesn't want to continue transmission, the TX request can alternatively be cleared through the `UART_IMSK_CLR.ETBEI` bit register. Transfers of data from the `UART_THR` register to the `UART_TSR` register set this status flag in the `UART_STAT` register again.

The `UART_STAT.TEMT` bit can be interrogated to see whether any transmission is ongoing. The `UART_STAT.TEMT` bit's sticky counterpart, `UART_STAT.TFI`, indicates if the transmit buffer has drained and can trigger a status interrupt, if required. When data is pending in either one of these registers, the `UART_STAT.TEMT` flag is low. As soon as all data has left the `UART_TSR` register, the `UART_STAT.TEMT` bit goes high again and indicates that all pending transmit operation (including stop bits) has finished. At that time it is safe to disable the `UART_CTL.EN` bit or to three-state off-chip line drivers. An interrupt can be generated by that time either through the status interrupt channel when the `UART_IMSK.ETFI` bit is set, or through the DMA controller when enabled by the `UART_IMSK.EDTPTI` bit.

When enabled by the `UART_IMSK.ETBEI` bit, the `UART_STAT.THRE` flag requests data along the peripheral command lines to the DMA controller (hereafter referred to as TXREQ). This signal is routed through the

DMA controller. If the associated DMA channel is enabled, the TXREQ signal functions as a DMA request, otherwise the DMA controller simply forwards it to the SEC. Alternatively the UART\_IMSK.ETXS bit can redirect the transmit interrupts to the UART status interrupt.

With interrupts disabled, these status flags can be polled to determine when data is ready to move. Note that because polling is processor intensive, it is not typically used in real-time signal processing environments. Since read operations from UART\_STAT registers have no side effects, different software threads can interrogate these registers without mutual impacts. Polling the SEC\_SSTATn register without enabling the interrupts by the SEC\_CCTL register is an alternate method of operation to consider. Software can write up to two words into the UART\_THR register before enabling the UART clock. As soon as the UART\_CTL.EN bit is set, those two words are sent.

## Receive Interrupts

Receive interrupts are enabled by the UART\_IMSK\_SET.ERBFI bit. If set, the UART\_STAT.DR flag requests an interrupt on the dedicated RXREQ output, indicating that new data is available in the UART\_RBR register. This signal is routed through the DMA controller. If the associated DMA channel is enabled, the RXREQ signal functions as a DMA request; otherwise the DMA controller simply forwards it to the SEC. Alternatively, if no DMA channel is assigned to the UART, the UART\_IMSK.ERXS bit can redirect the receive interrupts to the UART status interrupt. When software reads the UART\_RBR register, hardware clears the UART\_STAT.DR bit again, which, in turn, clears the receive interrupt request.

**Figure 19-13:** Receive Interrupts

The UART\_STAT.DR, UART\_STAT.ADDR, UART\_STAT.ASTKY, UART\_STAT.PE, UART\_STAT.FE, and UART\_STAT.BI bits are updated along with UART\_RBR register. The UART\_STAT.OE bit updated as soon as an overflow condition occurs (for example when a frame's stop bit is received and the receive FIFO is full). When the UART\_RBR register is not read in time, the received data is protected from being overwritten by

new data until the `UART_STAT.OE` bit is cleared by software. Only the content of the `UART_RSR` register can be overwritten in the overrun case.

The state of the 8-deep receive FIFO can be monitored by the `UART_STAT.RFCS` bit. The buffer's behavior is controlled by the `UARTx_CTL.RFIT` bit. If `UART_CTL.RFIT` is zero, the `UART_STAT.RFCS` bit is set when the receive buffer holds four or more words. If `UART_CTL.RFIT` is set, the `UART_STAT.RFCS` bit is set when the receive buffer holds seven or more words. The `UART_STAT.RFCS` bit is cleared by hardware when a core or DMA reads the `UART_RBR` register and when the buffer is flushed below the level of four (`UART_CTL.RFIT = 0`) or seven (`UART_CTL.RFIT = 1`). If the associated interrupt bit `UART_IMSK.ERFCI` is enabled, a status interrupt is reported when the `UART_STAT.RFCS` bit is set.

If errors are detected during reception, an interrupt can be requested from the status interrupt output. This status interrupt request goes directly to the SEC. Status interrupt requests are enabled by the `UART_IMSK_SET.ELSI` bit.

The controller detects the following error conditions, shown with their associated bits in the `UART_STAT` register.

- Overrun error (`UART_STAT.OE` bit)
- Parity error (`UART_STAT.PE` bit)
- Framing error/invalid stop bit (`UART_STAT.FE` bit)
- Break indicator (`UART_STAT.BI` bit)

## Status Interrupts

The UART status interrupt channels are used for the following purposes.

- Line status interrupts
- Flow control interrupts
- Receive FIFO threshold interrupts
- Transmission finished interrupt

Line status interrupts are enabled by the `UART_IMSK.ELSI` bit. If set, the status interrupt request is asserted with any of the `UART_STAT.BI`, `UART_STAT.FE`, `UART_STAT.PE`, or `UART_STAT.OE` receive errors bits. The error bits in the `UART_STAT` register are cleared by W1C operation. Once all error conditions are cleared, the interrupt request de-asserts.

The receive FIFO count interrupt is enabled by the `UART_IMSK_SET.ERFCI` bit. If set, a status interrupt is generated when the `UART_STAT.RFCS` is active. The `UART_STAT.RFCS` bit indicates a receive buffer threshold level. If the `UART_CTL.RFIT` bit is cleared, software can safely read two words out of the `UART_RBR` register by the time the `UART_STAT.RFCS` interrupt occurs. If the `UART_CTL.RFIT` bit is set, software can safely read four words. The interrupt and the `UART_STAT.RFCS` bit clear when the `UART_RBR` is read a sufficient number of times, so that the receive buffer drains below the threshold of two

(`UART_CTL.RFIT = 0`) or four (`UART_CTL.RFIT = 1`). Because in DMA mode a status service routine may not be permitted to read `UART_RBR`, this interrupt is only recommended in core mode. In DMA mode, use this functionality for error recovery only.

The flow control interrupts are enabled by the `UART_IMSK_SET.EDSSI` bit. If active, a status interrupt is generated when the sticky `UART_STAT.SCTS` bit register is set, indicating that the transmitter's `UART_CTS` input been re-asserted. A W1C operation to the `SCTS` bit clears the interrupt request.

A transmission finished interrupt is enabled by the `UART_IMSK_SET.ETFI` bit. If active, a status interrupt request is asserted when the `UART_STAT.TFI` bit is set. The `UART_STAT.TFI` is the sticky version of the `UART_STAT.TEMT` bit, indicating that a byte that started transmission has completely finished. The interrupt request is cleared by a W1C operation to the `UART_STAT.TFI` bit.

## Multi-Drop Bus Events

Several status bits and interrupt features in the `UART_STAT` and `UART_IMSK` registers facilitate efficient data handling in multi-drop bus mode. These include the address (`UART_STAT.ADDR`) bit, address sticky (`UART_STAT.ASTKY`) bit and enable address word interrupt (`UART_IMSK.EAWI`). One of the key features of the multi-drop bus protocol is its address bit, which signifies to the slaves that the master is transmitting an address word (to be read by all) or a data word (to be read by the addressed slave only). The UART hardware provides for an efficient method of handling the situation described above with the use of `UART_STAT.ASTKY` bit.

**NOTE:** The `UART_STAT.ASTKY` bit is used in multi-drop bus mode to indicate if a peripheral is currently being addressed. The `UART_STAT.ASTKY` bit is a sticky version of the `UART_STAT.ADDR` bit and is set by hardware whenever the `UART_STAT.ADDR` bit is set. It can only be cleared by software with a W1C operation. With the `ASTKY` bit set, words are received irrespective of the mode bit/address bit setting. With the `UART_STAT.ASTKY` bit cleared, only address words (mode bit = 1) are received and words with mode bit = 0 is ignored (not moved from the `UART_RSR` to the Receive FIFO) in MDB mode. This bit does not affect reception in non-MDB modes.

## UART Programming Model

The following sections provide basic procedures for configuring various UART operations.

### Detecting Autobaud

Please refer to [Autobaud Detection](#) for more information. The required steps are:

1. Ensure that the timer is disabled.
2. Configure the following bits: `UART_CTL.MOD = 00`, `UART_CTL.LOOP_EN = 1`, `UART_CTL.WLS = 11` (8-bit data), and `UART_CTL.EN = 1`

3. Configure the following bits: `TIMER_TMRn_CFG.TMODE = 1101`, `TIMER_TMRn_CFG.OUTDIS = 1`, `TIMER_TMRn_CFG.IRQMODE = 10` and enable the timer.
4. Send test data through the host device and wait for the timer interrupt and disable the timer.
5. The bit rate can be derived from the timer period register value according to the formula provided in the [Autobaud Detection](#) section.

## Using Common Initialization Steps

Certain steps are common to all UART modes, regardless of using the core or the DMA running the transfers.

1. All UART signals are multiplexed and compete with other functions at pin level. First, the port registers need to be programmed according to the guidelines in the PORTs chapter.
2. Program the `UART_CLK` register. Refer to [UART Bit Rate Generation](#).
3. Program the `UART_CTL` register and enable the UART clock.

*RESULT:*

## Using Core Transfers

A core transmit operation is done by writing data into the `UART_THR` register, when the `UART_STAT.THRE` bit is set. If the `UART_STAT.DR` bit is set, received data can be read from the `UART_RBR` register.

## Using DMA Transfers

1. Make sure that the `UART_IMSK.ETBEI` bit or the `UART_IMSK.ERBFI` bit, respectively, are cleared before configuring the DMA.
2. Configure the dedicated DMA channel.
3. Set the `UART_IMSK.ETBEI` bit or `UART_IMSK.ERBFI` bit to start the transfer.

## Using Interrupts

Each UART features three interrupt signal outputs.

1. Enable individual interrupts in the system event controller (SEC).
2. Register IRQ handlers.
3. Use the interrupts mask registers to enable specific IRQ events.

## Setting Up Hardware Flow Control

1. Configure automatic or manual hardware flow control for the receiver through the `UART_CTL.ARTS` bit, and/or the transmitter through the `UART_CTL.ACTS` bit.
2. Configure CTS and RTS polarity through the `UART_CTL.FCPOL` bit.

## UART Register Descriptions

UART (UART) contains the following registers.

**Table 19-8:** UART Module Registers

| Name          | Description                            |
|---------------|----------------------------------------|
| UART_REVID    | Revision ID Register                   |
| UART_CTL      | Control Register                       |

## Revision ID Register

The `UART_REVID` register provides revision information for the UART module.

**UART\_REVID: Revision ID Register - R/WE**

Reset = 0x0000 0004

**Figure 19-14:** UART\_REVID Register Diagram

**Table 19-9:** UART\_REVID Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:4     | MAJOR    | Major Version.          |
| 3:0     | REV      | Incremental Version.    |

## Control Register

The `UART_CTL` register provides enable/disable control for internal UART and for the IrDA mode of operation. This register also provides UART line control, permitting selection of the format of received and transmitted character frames. Modem feature control also is available from this register, including partial modem functionality to allow for hardware flow control and loopback mode.

UART\_CTL: Control Register - R/W

Reset = 0x0000 0000

**Table 19-10:** UART\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30      | RFRT     | Receive FIFO RTS Threshold.<br>The <code>UART_CTL.RFRT</code> bit controls <code>UART_RTS</code> pin assertion and de-assertion timing. This bit is ignored if <code>UART_CTL.ARTS</code> is cleared. If set, the <code>UART_RTS</code> pin is de-asserted when the receive buffer already holds seven words and an eighth start bit is detected. It is re-asserted when the FIFO contains seven words or less. If cleared, de-assert <code>UART_RTS</code> pin when the RX buffer already holds four words and a fifth start bit is detected. The <code>UART_RTS</code> pin is re-asserted when the RX buffer contains no more than 4 words. |
|         |          | 0 De-assert RTS if RX FIFO word count > 4; assert if <= 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
